ChatterBot is a Python library that makes it easy to generate automated responses to a user’s input. ChatterBot uses a selection of machine learning algorithms to produce different types of responses. This makes it easy for developers to create chat bots and automate conversations with users. For more details about the ideas and concepts behind ChatterBot see the process flow diagram.

An example of typical input would be something like this:

user: Good morning! How are you doing?
bot: I am doing very well, thank you for asking.
user: You're welcome.
bot: Do you like hats?
Language Independence

The language independent design of ChatterBot allows it to be trained to speak any language. Additionally, the machine-learning nature of ChatterBot allows an agent instance to improve it's own knowledge of possible responses as it interacts with humans and other sources of informative data.
ChatterBot is a Python library designed to make it easy to create software that can engage in conversation.

An *untrained instance* of ChatterBot starts off with no knowledge of how to communicate. Each time a user enters a *statement*, the library saves the text that they entered and the text that the statement was in response to. As ChatterBot receives more input the number of responses that it can reply and the accuracy of each response in relation to the input statement increase.

The program selects the closest matching *response* by searching for the closest matching known statement that matches the input, it then chooses a response from the selection of known responses to that statement.
CHAPTER 3

Process flow diagram
4.1 Installation

The recommended method for installing ChatterBot is by using pip.

4.1.1 Installing from PyPi

If you are just getting started with ChatterBot, it is recommended that you start by installing the latest version from the Python Package Index (PyPi). To install ChatterBot from PyPi using pip run the following command in your terminal.

```
pip install chatterbot
```

4.1.2 Installing from GitHub

You can install the latest development version of ChatterBot directly from GitHub using pip.

```
pip install git+git://github.com/gunthercox/ChatterBot.git@master
```

4.1.3 Installing from source

1. Download a copy of the code from GitHub. You may need to install git.

```
git clone https://github.com/gunthercox/ChatterBot.git
```

2. Install the code you have just downloaded using pip

```
pip install ./ChatterBot
```
4.1.3.1 Checking the version of ChatterBot that you have installed

If you already have ChatterBot installed and you want to check what version you have installed you can run the following command.

```
python -m chatterbot --version
```  

4.1.3.2 Upgrading ChatterBot to the latest version

Upgrading to Newer Releases

Like any software, changes will be made to ChatterBot over time. Most of these changes are improvements. Frequently, you don’t have to change anything in your code to benefit from a new release.

Occasionally there are changes that will require modifications in your code or there will be changes that make it possible for you to improve your code by taking advantage of new features.

To view a record of ChatterBot’s history of changes, visit the releases tab on ChatterBot’s GitHub page.

- https://github.com/gunthercox/ChatterBot/releases

Use the pip command to upgrade your existing ChatterBot installation by providing the –upgrade parameter:

```
pip install chatterbot --upgrade
```  

Also see Versioning for information about ChatterBot’s versioning policy.

4.2 Quick Start Guide

The first thing you’ll need to do to get started is install ChatterBot.

```
pip install chatterbot
```  

See Installation for options for alternative installation methods.

4.2.1 Create a new chat bot

**Note:** If you are using Python 2.7, be sure that the unicode header is the first line of your Python file:

```
# -*- coding: utf-8 -*-
```  

```python
from chatterbot import ChatBot
chatbot = ChatBot("Ron Obvious")
```

**Note:** The only required parameter for the ChatBot is a name. This can be anything you want.
4.2.2 Training your ChatBot

After creating a new ChatterBot instance it is also possible to train the bot. Training is a good way to ensure that the bot starts off with knowledge about specific responses. The current training method takes a list of statements that represent a conversation. Additional notes on training can be found in the Training documentation.

**Note:** Training is not required but it is recommended.

```python
from chatterbot.trainers import ListTrainer

conversation = [  
    "Hello",  
    "Hi there!",  
    "How are you doing?",  
    "I'm doing great.",  
    "That is good to hear",  
    "Thank you.",  
    "You're welcome."  
]

trainer = ListTrainer(chatbot)

trainer.train(conversation)
```

4.2.3 Get a response

```python
response = chatbot.get_response("Good morning!")
print(response)
```

4.3 ChatterBot Tutorial

This tutorial will guide you through the process of creating a simple command-line chat bot using ChatterBot.

4.3.1 Getting help

If you’re having trouble with this tutorial, you can post a message on Gitter to chat with other ChatterBot users who might be able to help.

You can also ask questions on Stack Overflow under the chatterbot tag.

If you believe that you have encountered an error in ChatterBot, please open a ticket on GitHub: https://github.com/gunthercox/ChatterBot/issues/new

4.3.2 Installing ChatterBot

You can install ChatterBot on your system using Python’s pip command.

```
pip install chatterbot
```

See Installation for alternative installation options.
4.3.3 Creating your first chat bot

Create a new file named `chatbot.py`. Then open `chatbot.py` in your editor of choice.

Before we do anything else, ChatterBot needs to be imported. The import for ChatterBot should look like the following line.

```python
from chatterbot import ChatBot
```

Create a new instance of the `ChatBot` class.

```python
bot = ChatBot('Norman')
```

This line of code has created a new chat bot named `Norman`. There is a few more parameters that we will want to specify before we run our program for the first time.

4.3.3.1 Setting the storage adapter

ChatterBot comes with built-in adapter classes that allow it to connect to different types of databases. In this tutorial, we will be using the `SQLStorageAdapter` which allows the chat bot to connect to SQL databases. By default, this adapter will create a SQLite database.

The `database` parameter is used to specify the path to the database that the chat bot will use. For this example we will call the database `database.sqlite3`. this file will be created automatically if it doesn’t already exist.

```python
bot = ChatBot(
    'Norman',
    storage_adapter='chatterbot.storage.SQLStorageAdapter',
    database_uri='./database.sqlite3'
)
```

**Note:** The SQLStorageAdapter is ChatterBot’s default adapter. If you do not specify an adapter in your constructor, the SQLStorageAdapter adapter will be used automatically.

4.3.3.2 Input and output adapters

Next, we will add in parameters to specify the input and output terminal adapter. The input terminal adapter simply reads the user’s input from the terminal. The output terminal adapter prints the chat bot’s response.

```python
bot = ChatBot(
    'Norman',
    storage_adapter='chatterbot.storage.SQLStorageAdapter',
    input_adapter='chatterbot.input.TerminalAdapter',
    output_adapter='chatterbot.output.TerminalAdapter',
    database_uri='./database.sqlite3'
)
```

4.3.3.3 Specifying logic adapters

The `logic_adapters` parameter is a list of logic adapters. In ChatterBot, a logic adapter is a class that takes an input statement and returns a response to that statement.
You can choose to use as many logic adapters as you would like. In this example we will use two logic adapters. The `TimeLogicAdapter` returns the current time when the input statement asks for it. The `MathematicalEvaluation` adapter solves math problems that use basic operations.

```python
bot = ChatBot(
    'Norman',
    storage_adapter='chatterbot.storage.SQLStorageAdapter',
    input_adapter='chatterbot.input.TerminalAdapter',
    output_adapter='chatterbot.output.TerminalAdapter',
    logic_adapters=[
        'chatterbot.logic.MathematicalEvaluation',
        'chatterbot.logic.TimeLogicAdapter'
    ],
    database_uri='./database.sqlite3'
)
```

### 4.3.3.4 Getting a response from your chat bot

Next, you will want to create a while loop for your chat bot to run in. By breaking out of the loop when specific exceptions are triggered, we can exit the loop and stop the program when a user enters `ctrl+c`.

```python
while True:
    try:
        bot_input = bot.get_response(None)
    except (KeyboardInterrupt, EOFError, SystemExit):
        break
```

### 4.3.3.5 Training your chat bot

At this point your chat bot, Norman will learn to communicate as you talk to him. You can speed up this process by training him with examples of existing conversations.

```python
from chatterbot.training import ListTrainer

trainer = ListTrainer(bot)

trainer.train([
    'How are you?',
    'I am good.',
    'That is good to hear.',
    'Thank you',
    'You are welcome.',
])
```

You can run the training process multiple times to reinforce preferred responses to particular input statements. You can also run the train command on a number of different example dialogs to increase the breadth of inputs that your chat bot can respond to.

This concludes this ChatterBot tutorial. Please see other sections of the documentation for more details and examples.

Up next: *Examples*
4.4 Examples

The following examples are available to help you get started with ChatterBot.

4.4.1 Simple Example

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot
from chatterbot.trainers import ListTrainer

# Create a new chat bot named Charlie
chatbot = ChatBot('Charlie')
trainer = ListTrainer(chatbot)
trainer.train(['Hi, can I help you?',
               'Sure, I’d like to book a flight to Iceland.',
               'Your flight has been booked.'])

# Get a response to the input text 'I would like to book a flight.'
response = chatbot.get_response('I would like to book a flight.')
print(response)
```

4.4.2 Terminal Example

This example program shows how to create a simple terminal client that allows you to communicate with your chat bot by typing into your terminal.

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot

# Uncomment the following lines to enable verbose logging
# import logging
# logging.basicConfig(level=logging.INFO)

# Create a new instance of a ChatBot
bot = ChatBot('Terminal',
              storage_adapter='chatterbot.storage.SQLStorageAdapter',
              logic_adapters=['chatterbot.logic.MathematicalEvaluation',
                               'chatterbot.logic.TimeLogicAdapter',
                               'chatterbot.logic.BestMatch'],
              input_adapter='chatterbot.input.TerminalAdapter',
              output_adapter='chatterbot.output.TerminalAdapter',
              database_uri='file:../database.db')

print("Type something to begin...")
```

(continues on next page)
The following loop will execute each time the user enters input:

```python
while True:
    try:
        # We pass None to this method because the parameter
        # is not used by the TerminalAdapter
        bot_input = bot.get_response(None)

        # Press ctrl-c or ctrl-d on the keyboard to exit
        except (KeyboardInterrupt, EOFError, SystemExit):
            break
```

### 4.4.3 Using MongoDB

Before you can use ChatterBot’s built-in adapter for MongoDB, you will need to install MongoDB. Make sure MongoDB is running in your environment before you execute your program. To tell ChatterBot to use this adapter, you will need to set the `storage_adapter` parameter.

```python
storage_adapter = "chatterbot.storage.MongoDatabaseAdapter"
```

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot

# Uncomment the following lines to enable verbose logging
# import logging
# logging.basicConfig(level=logging.INFO)

# Create a new ChatBot instance
bot = ChatBot(
    'Terminal',
    storage_adapter='chatterbot.storage.MongoDatabaseAdapter',
    logic_adapters=[
        'chatterbot.logic.BestMatch'
    ],
    filters=[
        'chatterbot.filters.RepetitiveResponseFilter'
    ],
    input_adapter='chatterbot.input.TerminalAdapter',
    output_adapter='chatterbot.output.TerminalAdapter',
    database_uri='mongodb://localhost:27017/chatterbot-database'
)

print('Type something to begin...')

while True:
    try:
        bot_input = bot.get_response(None)

        # Press ctrl-c or ctrl-d on the keyboard to exit
    except (KeyboardInterrupt, EOFError, SystemExit):
        break
```

### 4.4. Examples

15
4.4.4 Time and Mathematics Example

ChatterBot has natural language evaluation capabilities that allow it to process and evaluate mathematical and time-based inputs.

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot

bot = ChatBot(
    "Math & Time Bot",
    logic_adapters=[
        "chatterbot.logic.MathematicalEvaluation",
        "chatterbot.logic.TimeLogicAdapter"
    ],
    input_adapter="chatterbot.input.VariableInputTypeAdapter",
    output_adapter="chatterbot.output.OutputAdapter"
)

# Print an example of getting one math based response
response = bot.get_response("What is 4 + 9?")
print(response)

# Print an example of getting one time based response
response = bot.get_response("What time is it?")
print(response)
```

4.4.5 Gitter Example

ChatterBot works great with chat rooms. An example for the popular service Gitter demonstrates this.

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot
from chatterbot.input import Gitter
from settings import GITTER

chatbot = ChatBot(
    'GitterBot',
    gitter_room=GITTER['ROOM'],
    gitter_api_token=GITTER['API_TOKEN'],
    gitter_only_respond_to_mentions=False,
    input_adapter='chatterbot.input.Gitter',
    output_adapter='chatterbot.output.Gitter'
)

trainer = ChatterBotCorpusTrainer(chatbot)
trainer.train('chatterbot.corpus.english')

# The following loop will execute each time the user enters input
```

(continues on next page)
4.4.6 Using SQL Adapter

ChatterBot data can be saved and retrieved from SQL databases.

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot

# Uncomment the following lines to enable verbose logging
# import logging
# logging.basicConfig(level=logging.INFO)

# Create a new instance of a ChatBot
bot = ChatBot(
    "SQLMemoryTerminal",
    storage_adapter='chatterbot.storage.SQLStorageAdapter',
    logic_adapters=[
        "chatterbot.logic.MathematicalEvaluation",
        "chatterbot.logic.TimeLogicAdapter",
        "chatterbot.logic.BestMatch"
    ],
    input_adapter="chatterbot.input.TerminalAdapter",
    output_adapter="chatterbot.output.TerminalAdapter",
)

print("Type something to begin...")

# The following loop will execute each time the user enters input
while True:
    try:
        # We pass None to this method because the parameter
        # is not used by the TerminalAdapter
        bot_input = bot.get_response(None)

        # Press ctrl-c or ctrl-d on the keyboard to exit
    except (KeyboardInterrupt, EOFError, SystemExit):
        break
```

4.4.7 Read only mode

Your chat bot will learn based on each new input statement it receives. If you want to disable this learning feature after your bot has been trained, you can set `read_only=True` as a parameter when initializing the bot.

```python
chatbot = ChatBot("Johnny Five", read_only=True)
```
4.4.8 More Examples

Even more examples can be found in the examples directory in on GitHub: https://github.com/gunthercox/ChatterBot/tree/master/examples

4.5 Training

ChatterBot includes tools that help simplify the process of training a chat bot instance. ChatterBot’s training process involves loading example dialog into the chat bot’s database. This either creates or builds upon the graph data structure that represents the sets of known statements and responses. When a chat bot trainer is provided with a data set, it creates the necessary entries in the chat bot’s knowledge graph so that the statement inputs and responses are correctly represented.

Several training classes come built-in with ChatterBot. These utilities range from allowing you to update the chat bot’s database knowledge graph based on a list of statements representing a conversation, to tools that allow you to train your bot based on a corpus of pre-loaded training data.

You can also create your own training class. This is recommended if you wish to train your bot with data you have stored in a format that is not already supported by one of the pre-built classes listed below.

4.5.1 Setting the training class

ChatterBot comes with training classes built in, or you can create your own if needed. To use a training class you call train() on an instance that has been initialized with your chat bot.

4.5.2 Training classes

4.5.2.1 Training via list data

chatterbot.trainers.ListTrainer(chatbot, **kwargs)

Allows a chat bot to be trained using a list of strings where the list represents a conversation.

For the training process, you will need to pass in a list of statements where the order of each statement is based on its placement in a given conversation.

For example, if you were to run bot of the following training calls, then the resulting chatterbot would respond to both statements of “Hi there!” and “Greetings!” by saying “Hello”.

```python
from chatterbot.trainers import ListTrainer

chatbot = ChatBot("Training Example")
trainer = ListTrainer(chatbot)

trainer.train(["Hi there!", "Hello",])
trainer.train(["Greetings!",]
```

(continues on next page)
You can also provide longer lists of training conversations. This will establish each item in the list as a possible response to it’s predecessor in the list.

```python
trainer.train([  
    "Hello",
    "How are you?",
    "I am good.",
    "That is good to hear.",
    "Thank you",
    "You are welcome."
])
```

### 4.5.2.2 Training with corpus data

`chatterbot.trainers.ChatterBotCorpusTrainer(storage, **kwargs)`

Allows the chat bot to be trained using data from the ChatterBot dialog corpus.

ChatterBot comes with a corpus data and utility module that makes it easy to quickly train your bot to communicate. To do so, simply specify the corpus data modules you want to use.

```python
from chatterbot.trainers import ChatterBotCorpusTrainer
chatbot = ChatBot("Training Example")
trainer = ChatterBotCorpusTrainer(chatbot)
trainer.train("chatterbot.corpus.english")
```

#### Specifying corpus scope

It is also possible to import individual subsets of ChatterBot’s corpus at once. For example, if you only wish to train based on the english greetings and conversations corpora then you would simply specify them.

```python
trainer.train([  
    "chatterbot.corpus.english.greetings",
    "chatterbot.corpus.english.conversations"
])
```

You can also specify file paths to corpus files or directories of corpus files when calling the `train` method.

```python
trainer.train([  
    "/data/greetings_corpus/custom.corpus.json",
    "/data/my_corpus/"
])
```

### 4.5.2.3 Training with the Twitter API

`chatterbot.trainers.TwitterTrainer(storage, **kwargs)`

Allows the chat bot to be trained using data gathered from Twitter.
Parameters

- **random_seed_word** – The seed word to be used to get random tweets from the Twitter API. This parameter is optional. By default it is the word ‘random’.

- **twitter_lang** – Language for results as ISO 639-1 code. This parameter is optional. Default is None (all languages).

Create a new app using your Twitter account. Once created, it will provide you with the following credentials that are required to work with the Twitter API.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>twitter_consumer_key</td>
<td>Consumer key of twitter app.</td>
</tr>
<tr>
<td>twitter_consumer_secret</td>
<td>Consumer secret of twitter app.</td>
</tr>
<tr>
<td>twitter_access_token_key</td>
<td>Access token key of twitter app.</td>
</tr>
<tr>
<td>twitter_access_token_secret</td>
<td>Access token secret of twitter app.</td>
</tr>
</tbody>
</table>

Twitter training example

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot
from chatterbot.trainers import TwitterTrainer
from settings import TWITTER
import logging

logging.basicConfig(level=logging.INFO)
chatbot = ChatBot(
    "TwitterBot",
    logic_adapters=[
        "chatterbot.logic.BestMatch"
    ],
    input_adapter="chatterbot.input.TerminalAdapter",
    output_adapter="chatterbot.output.TerminalAdapter",
    database_uri="./twitter-database.db",
    twitter_consumer_key=TWITTER["CONSUMER_KEY"],
    twitter_consumer_secret=TWITTER['CONSUMER_SECRET'],
    twitter_access_token_key=TWITTER['ACCESS_TOKEN'],
    twitter_access_token_secret=TWITTER['ACCESS_TOKEN_SECRET']
)
```

(continues on next page)
4.5.2.4 Training with the Ubuntu dialog corpus

**Warning:** The Ubuntu dialog corpus is a massive data set. Developers will currently experience significantly decreased performance in the form of delayed training and response times from the chat bot when using this corpus.

chatterbot.trainers.UbuntuCorpusTrainer(storage, **kwargs)

Allow chatbots to be trained with the data from the Ubuntu Dialog Corpus.

This training class makes it possible to train your chat bot using the Ubuntu dialog corpus. Because of the file size of the Ubuntu dialog corpus, the download and training process may take a considerable amount of time.

This training class will handle the process of downloading the compressed corpus file and extracting it. If the file has already been downloaded, it will not be downloaded again. If the file is already extracted, it will not be extracted again.

4.5.3 Creating a new training class

You can create a new trainer to train your chat bot from your own data files. You may choose to do this if you want to train your chat bot from a data source in a format that is not directly supported by ChatterBot.

Your custom trainer should inherit chatterbot.trainers.Trainer class. Your trainer will need to have a method named train, that can take any parameters you choose.

Take a look at the existing trainer classes on GitHub for examples.

4.6 Preprocessors

ChatterBot’s preprocessors are simple functions that modify the input statement that a chat bot receives before the statement gets processed by the logic adapter.

Here is an example of how to set preprocessors. The preprocessors parameter should be a list of strings of the import paths to your preprocessors.
4.6.1 Preprocessor functions

ChatterBot comes with several built-in preprocessors.

chatterbot.preprocessors.clean_whitespace(chatbot, statement)
Remove any consecutive whitespace characters from the statement text.

chatterbot.preprocessors.unescape_html(chatbot, statement)
Convert escaped html characters into unescaped html characters. For example: “&lt;b&gt;” becomes “<b>”.

chatterbot.preprocessors.convert_to_ascii(chatbot, statement)
Converts unicode characters to ASCII character equivalents. For example: “på féderal” becomes “pa federal”.

4.6.2 Creating new preprocessors

It is simple to create your own preprocessors. A preprocessor is just a function with a few requirements.

1. It must take two parameters, the first is a ChatBot instance, the second is a Statement instance.
2. It must return a statement instance.

4.7 Logic Adapters

Logic adapters determine the logic for how ChatterBot selects a response to a given input statement.

4.7.1 How logic adapters select a response

A typical logic adapter designed to return a response to an input statement will use two main steps to do this. The first step involves searching the database for a known statement that matches or closely matches the input statement. Once a match is selected, the second step involves selecting a known response to the selected match. Frequently, there will be a number of existing statements that are responses to the known match.

To help with the selection of the response, several methods are built into ChatterBot for selecting a response from the available options.

4.7.1.1 Response selection methods

Response selection methods determines which response should be used in the event that multiple responses are generated within a logic adapter.

chatterbot.response_selection.get_first_response(input_statement, response_list, storage=None)

Parameters

• input_statement (Statement) – A statement, that closely matches an input to the chat bot.
• response_list (list) – A list of statement options to choose a response from.
• storage (StorageAdapter) – An instance of a storage adapter to allow the response selection method to access other statements if needed.

Returns Return the first statement in the response list.

Return type Statement
chatterbot.response_selection.get_most_frequent_response(input_statement, response_list, storage=None)

Parameters

- **input_statement** (Statement) – A statement, that closely matches an input to the chat bot.
- **response_list** (list) – A list of statement options to choose a response from.
- **storage** (StorageAdapter) – An instance of a storage adapter to allow the response selection method to access other statements if needed.

Returns The response statement with the greatest number of occurrences.

Return type Statement

chatterbot.response_selection.get_random_response(input_statement, response_list, storage=None)

Parameters

- **input_statement** (Statement) – A statement, that closely matches an input to the chat bot.
- **response_list** (list) – A list of statement options to choose a response from.
- **storage** (StorageAdapter) – An instance of a storage adapter to allow the response selection method to access other statements if needed.

Returns Choose a random response from the selection.

Return type Statement

Use your own response selection method

You can create your own response selection method and use it as long as the function takes two parameters (a statements and a list of statements). The method must return a statement.

```python
def select_response(statement, statement_list, storage=None):
    # Your selection logic
    return selected_statement
```

4.7.1.2 Setting the response selection method

To set the response selection method for your chat bot, you will need to pass the `response_selection_method` parameter to your chat bot when you initialize it. An example of this is shown below.

```python
from chatterbot import ChatBot
from chatterbot.response_selection import get_most_frequent_response

chatbot = ChatBot(
    # ...
    response_selection_method=get_most_frequent_response
)
```
4.7.1.3 Response selection in logic adapters

When a logic adapter is initialized, the response selection method parameter that was passed to it can be called using `self.select_response` as shown below.

```python
response = self.select_response(
    input_statement,
    list_of_response_options,
    self.chatbot.storage
)
```

4.7.1.4 Selecting a response from multiple logic adapters

The `generate_response` method is used to select a single response from the responses returned by all of the logic adapters that the chat bot has been configured to use. Each response returned by the logic adapters includes a confidence score that indicates the likeliness that the returned statement is a valid response to the input.

**Response selection**

The `generate_response` will return the response statement that has the greatest confidence score. The only exception to this is a case where multiple logic adapters return the same statement and therefore agree on that response.

For this example, consider a scenario where multiple logic adapters are being used. Assume the following results were returned by a chat bot’s logic adapters.

<table>
<thead>
<tr>
<th>Confidence</th>
<th>Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.2</td>
<td>Good morning</td>
</tr>
<tr>
<td>0.5</td>
<td>Good morning</td>
</tr>
<tr>
<td>0.7</td>
<td>Good night</td>
</tr>
</tbody>
</table>

In this case, two of the logic adapters have generated the same result. When multiple logic adapters come to the same conclusion, that statement is given priority over another response with a possibly higher confidence score. The fact that the multiple adapters agreed on a response is a significant indicator that a particular statement has a greater probability of being a more accurate response to the input.

When multiple adapters agree on a response, the greatest confidence score that was generated for that response will be returned with it.

4.7.2 Creating a new logic adapter

You can write your own logic adapters by creating a new class that inherits from `LogicAdapter` and overrides the necessary methods established in the `LogicAdapter` base class.

4.7.2.1 Logic adapter methods

```python
class chatterbot.logic.LogicAdapter(**kwargs)
    This is an abstract class that represents the interface that all logic adapters should implement.

    Parameters
    ----------
    • `statement_comparison_function` – The dot-notated import path to a statement comparison function. Defaults to `levenshtein_distance`.
```

exception EmptyDatasetException (value='An empty set was received when at least one statement was expected. ‘)

can_process (statement)
A preliminary check that is called to determine if a logic adapter can process a given statement. By default, this method returns true but it can be overridden in child classes as needed.

Return type bool
class_name
Return the name of the current logic adapter class. This is typically used for logging and debugging.

get_initialization_functions ()
Return a dictionary of functions to be run once when the chat bot is instantiated.

process (statement)
Override this method and implement your logic for selecting a response to an input statement.

A confidence value and the selected response statement should be returned. The confidence value represents a rating of how accurate the logic adapter expects the selected response to be. Confidence scores are used to select the best response from multiple logic adapters.

The confidence value should be a number between 0 and 1 where 0 is the lowest confidence level and 1 is the highest.

Parameters statement (Statement) – An input statement to be processed by the logic adapter.

Return type Statement

4.7.2.2 Example logic adapter

```python
from chatterbot.logic import LogicAdapter

class MyLogicAdapter(LogicAdapter):
    def __init__(self, **kwargs):
        super(MyLogicAdapter, self).__init__(**kwargs)

    def can_process(self, statement):
        return True

    def process(self, statement):
        import random

        # Randomly select a confidence between 0 and 1
        confidence = random.uniform(0, 1)

        # For this example, we will just return the input as output
        selected_statement = statement
        selected_statement.confidence = confidence

        return selected_statement
```

4.7. Logic Adapters
4.7.2.3 Directory structure

If you create your own logic adapter you will need to have it in a separate file from your chat bot. Your directory setup should look something like the following:

```
project_directory
    cool_chatbot.py
    cool_adapter.py
```

Then assuming that you have a class named `MyLogicAdapter` in your `cool_adapter.py` file, you should be able to specify the following when you initialize your chat bot.

```
ChatBot(
    # ...
    logic_adapters=[
                   {
                     'import_path': 'cool_adapter.MyLogicAdapter'
                   }
    ]
)
```

4.7.2.4 Responding to specific input

If you want a particular logic adapter to only respond to a unique type of input, the best way to do this is by overriding the `can_process` method on your own logic adapter.

Here is a simple example. Let’s say that we only want this logic adapter to generate a response when the input statement starts with “Hey Mike”. This way, statements such as “Hey Mike, what time is it?” will be processed, but statements such as “Do you know what time it is?” will not be processed.

```
def can_process(self, statement):
    if statement.text.startswith('Hey Mike')
        return True
    else:
        return False
```

4.7.2.5 Interacting with services

In some cases, it is useful to have a logic adapter that can interact with an external service or api in order to complete its task. Here is an example that demonstrates how this could be done. For this example we will use a fictitious API endpoint that returns the current temperature.

```
def can_process(self, statement):
    """
    Return true if the input statement contains 'what' and 'is' and 'temperature'.
    """
    words = ['what', 'is', 'temperature']
    if all(x in statement.text.split() for x in words)
        return True
    else:
        return False
```

(continues on next page)
from chatterbot.conversation import Statement
import requests

# Make a request to the temperature API
response = requests.get('https://api.temperature.com/current?units=celsius')
data = response.json()

# Let's base the confidence value on if the request was successful
if response.status_code == 200:
    confidence = 1
else:
    confidence = 0

temperature = data.get('temperature', 'unavailable')

response_statement = Statement('The current temperature is {}'.format(temperature))

return confidence, response_statement

4.7.2.6 Providing extra arguments

All key word arguments that have been set in your ChatBot class’s constructor will also be passed to the __init__ method of each logic adapter. This allows you to access these variables if you need to use them in your logic adapter. (An API key might be an example of a parameter you would want to access here.)

You can override the __init__ method on your logic adapter to store additional information passed to it by the ChatBot class.

class MyLogicAdapter(LogicAdapter):
    def __init__(self, **kwargs):
        super(MyLogicAdapter, self).__init__(**kwargs)

        self.api_key = kwargs.get('secret_key')

The secret_key variable would then be passed to the ChatBot class as shown below.

chatbot = ChatBot(
    # ...
    secret_key='************************'
)

The logic adapter that your bot uses can be specified by setting the logic_adapters parameter to the import path of the logic adapter you want to use.

It is possible to enter any number of logic adapters for your bot to use. If multiple adapters are used, then the bot will return the response with the highest calculated confidence value. If multiple adapters return the same confidence, then the adapter that is entered into the list first will take priority.

chatbot = ChatBot(
    "My ChatterBot",
    logic_adapters=[
        "chatterbot.logic.BestMatch"
    ]
)
4.7.3 Best Match Adapter

chatterbot.logic.BestMatch(**kwargs)

A logic adapter that returns a response based on known responses to the closest matches to the input statement.

The BestMatch logic adapter selects a response based on the best known match to a given statement.

4.7.3.1 How it works

The best match adapter uses a function to compare the input statement to known statements. Once it finds the closest match to the input statement, it uses another function to select one of the known responses to that statement.

4.7.3.2 Setting parameters

```python
chatbot = ChatBot(  
    "My ChatterBot",  
    logic_adapters=[  
        {  
            "import_path": "chatterbot.logic.BestMatch",  
            "statement_comparison_function": "chatterbot.comparisons.levenshtein_distance",  
            "response_selection_method": "chatterbot.response_selection.get_first_response"  
        }  
    ]
)
```

Note: The values for `response_selection_method` and `statement_comparison_function` can be a string of the path to the function, or a callable.

See the Statement comparison documentation for the list of functions included with ChatterBot.

See the Response selection methods documentation for the list of response selection methods included with ChatterBot.

4.7.4 Time Logic Adapter

chatterbot.logic.TimeLogicAdapter(**kwargs)

The TimeLogicAdapter returns the current time.

Kwargs

- `positive` (list) – The time-related questions used to identify time questions. Defaults to a list of English sentences.
- `negative` (list) – The non-time-related questions used to identify time questions. Defaults to a list of English sentences.

The TimeLogicAdapter identifies statements in which a question about the current time is asked. If a matching question is detected, then a response containing the current time is returned.

User: What time is it?
Bot: The current time is 4:45PM.
4.7.5 Mathematical Evaluation Adapter

chatterbot.logic.MathematicalEvaluation(**kwargs)

The MathematicalEvaluation logic adapter parses input to determine whether the user is asking a question that requires math to be done. If so, the equation is extracted from the input and returned with the evaluated result.

For example: User: ‘What is three plus five?’ Bot: ‘Three plus five equals eight’

Kwargs

• language (str) – The language is set to ‘ENG’ for English by default.

The MathematicalEvaluation logic adapter checks a given statement to see if it contains a mathematical expression that can be evaluated. If one exists, then it returns a response containing the result. This adapter is able to handle any combination of word and numeric operators.

User: What is four plus four?
Bot: (4 + 4) = 8

4.7.6 Low Confidence Response Adapter

This adapter returns a specified default response if a response can not be determined with a high amount of confidence.

chatterbot.logic.LowConfidenceAdapter(**kwargs)

Returns a default response with a high confidence when a high confidence response is not known.

Kwargs

• threshold (float) – The low confidence value that triggers this adapter. Defaults to 0.65.
• default_response (str) or (iterable)– The response returned by this logic adapter.
• response_selection_method (str) or (callable) The a response selection method. Defaults to get_first_response.

4.7.6.1 Low confidence response example

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot
from chatterbot.trainers import ListTrainer

# Create a new instance of a ChatBot
bot = ChatBot('Default Response Example Bot',
              storage_adapter='chatterbot.storage.SQLStorageAdapter',
              logic_adapters=[
                
                {
                    'import_path': 'chatterbot.logic.BestMatch'
                },
                
                {
                    'import_path': 'chatterbot.logic.LowConfidenceAdapter',
                    'threshold': 0.65,
                    'default_response': 'I am sorry, but I do not understand.'
                }
            ]
```

trainer = ListTrainer(bot)

# Train the chat bot with a few responses
trainer.train(['How can I help you?',
               'I want to create a chat bot',
               'Have you read the documentation?',
               'No, I have not',
               'This should help get you started: http://chatterbot.rtfd.org/en/latest/quickstart.html'])

# Get a response for some unexpected input
response = bot.get_response('How do I make an omelette?')
print(response)

### 4.7.7 Specific Response Adapter

If the input that the chat bot receives, matches the input text specified for this adapter, the specified response will be returned.

```python
chatterbot.logic.SpecificResponseAdapter(**kwargs)
```

Return a specific response to a specific input.

**Kwargs**

- `input_text (str)` – The input text that triggers this logic adapter.
- `output_text (str)` – The output text returned by this logic adapter.

#### 4.7.7.1 Specific response example

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot

# Create a new instance of a ChatBot
bot = ChatBot(
    'Exact Response Example Bot',
    storage_adapter='chatterbot.storage.SQLStorageAdapter',
    logic_adapters=[
        {  
            'import_path': 'chatterbot.logic.BestMatch'  
        },
        {  
            'import_path': 'chatterbot.logic.SpecificResponseAdapter',
            'input_text': 'Help me!',
            'output_text': 'Ok, here is a link: http://chatterbot.rtfd.org'
        }
    ]
)
```

(continues on next page)
# Get a response given the specific input
response = bot.get_response('Help me!')
print(response)

## 4.8 Input Adapters

ChatterBot’s input adapters are designed to allow a chat bot to have a versatile method of receiving or retrieving input from a given source.

### 4.8.1 Creating a new input adapter

You can write your own input adapters by creating a new class that inherits from `InputAdapter` and overrides the necessary methods established in the base `InputAdapter` class.

```python
from chatterbot.adapters import Adapter

class InputAdapter(Adapter):
    
    """
    This is an abstract class that represents the interface that all input adapters should implement.
    """

    def process_input(self, statement):
        """
        Returns a statement object based on the input source.
        """
        raise self.AdapterMethodNotImplementedError()
```

The goal of an input adapter is to get input from some source, and then to convert it into a format that ChatterBot can understand. This format is the `Statement` object found in ChatterBot’s `conversation` module.

### 4.8.2 Variable input type adapter

Chatterbot.input.**VariableInputTypeAdapter**(**kwargs)

This is an abstract class that represents the interface that all input adapters should implement.

The variable input type adapter allows the chat bot to accept a number of different input types using the same adapter. This adapter accepts strings, dictionaries and `Statements`.

```python
chatbot = ChatBot(
    "My ChatterBot",
    input_adapter="chatterbot.input.VariableInputTypeAdapter"
)
```
4.8.3 Terminal input adapter

chatterbot.input.TerminialAdapter(**kwargs)

A simple adapter that allows ChatterBot to communicate through the terminal.

The input terminal adapter allows a user to type into their terminal to communicate with the chat bot.

```python
chatbot = ChatBot(  
    "My ChatterBot",  
    input_adapter="chatterbot.input.TerminalAdapter"
)
```

4.8.4 Gitter input adapter

chatterbot.input.Gitter(**kwargs)

An input adapter that allows a ChatterBot instance to get input statements from a Gitter room.

```python
chatbot = ChatBot(  
    "My ChatterBot",  
    input_adapter="chatterbot.input.Gitter",  
    gitter_api_token="my-gitter-api-token",  
    gitter_room="my-room-name",  
    gitter_only_respond_to_mentions=True,
)
```

4.8.5 Mailgun input adapter

chatterbot.input.Mailgun(**kwargs)

Get input from Mailgun.

The Mailgun adapter allows a chat bot to receive emails using the Mailgun API.

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot
from settings import MAILGUN

# Change these to match your own email configuration
FROM_EMAIL = "mailgun@salvius.org"
RECIPIENTS = ["gunthercx@gmail.com"]

bot = ChatBot(  
    "Mailgun Example Bot",  
    mailgun_from_address=FROM_EMAIL,  
    mailgun_api_key=MAILGUN["CONSUMER_KEY"],  
    mailgun_api_endpoint=MAILGUN["API_ENDPOINT"],
)  
```
```python
mailgun_recipients=RECIPIENTS,
input_adapter="chatterbot.input.Mailgun",
output_adapter="chatterbot.output.Mailgun",
storage_adapter="chatterbot.storage.SQLStorageAdapter",
database_uri="../database.db"
)

# Send an example email to the address provided
response = bot.get_response("How are you?")
print("Check your inbox at ", RECIPIENTS)
```

4.8.6 Microsoft Bot Framework input adapter

```python
cchatbot.input.Microsoft(**kwargs)
```

An input adapter that allows a ChatterBot instance to get input statements from a Microsoft Bot using Directline client protocol. https://docs.botframework.com/en-us/restapi/directline/#navtitle

This is an input adapter that allows a ChatterBot instance to communicate through Microsoft using direct line client protocol.

Be sure to also see the documentation for the Microsoft output adapter.

```python
chatbot = ChatBot(
    "My ChatterBot",
    input_adapter="chatterbot.input.Microsoft",
directline_host="https://directline.botframework.com",
directline_conversation_id="IEyJvnDULgn",
direct_line_token_or_secret="RCurR_XV92A.cwA.BKA.˓
→iaJrC8xpy8qbOF5xnRvtxCX7CZj0LdjAPGfiCpg4Fv0",
)
```

4.9 Output Adapters

4.9.1 Creating a new output adapter

You can write your own output adapters by creating a new class that inherits from chatterbot.output.OutputAdapter and overrides the necessary methods established in the OutputAdapter class.

To create your own output adapter you must override the process_response method to return a Statement object.

Note that you may need to extend the __init__ method of your custom output adapter if you intend to save a kwarg parameter that was passed into the chat bot’s constructor. (An API key might be an example of a parameter you would want to access here.)

```python
from chatterbot.adapters import Adapter

class OutputAdapter(Adapter):
    
    ""
    A generic class that can be overridden by a subclass to provide extended functionality, such as delivering a response to an API endpoint.
    ""
```

(continues on next page)
def process_response(self, statement):
    """
    Override this method in a subclass to implement customized functionality.
    :param statement: The statement that the chat bot has produced in response to some input.
    :returns: The response statement.
    """
    return statement

4.9.2 Output format adapter

chatterbot.output.OutputAdapter(**kwargs)

A generic class that can be overridden by a subclass to provide extended functionality, such as delivering a response to an API endpoint.

The output adapter allows the chat bot to return a response in as a Statement object.

    chatbot = ChatBot(
        "My ChatterBot",
        output_adapter="chatterbot.output.OutputAdapter",
        output_format="text"
    )

4.9.3 Terminal output adapter

chatterbot.output.TerminalAdapter(**kwargs)

A simple adapter that allows ChatterBot to communicate through the terminal.

The output terminal adapter allows a user to type into their terminal to communicate with the chat bot.

    chatbot = ChatBot(
        "My ChatterBot",
        output_adapter="chatterbot.output.TerminalAdapter"
    )

4.9.4 Gitter output adapter

chatterbot.output.Gitter(**kwargs)

An output adapter that allows a ChatterBot instance to send responses to a Gitter room.

    chatbot = ChatBot(
        "My ChatterBot",
        output_adapter="chatterbot.output.Gitter",
        gitter_api_token="my-gitter-api-token",
        gitter_room="my-room-name",
        gitter_only_respond_to_mentions=True,
    )
4.9.5 Microsoft Bot Framework output adapter

chatterbot.output.Microsoft(**kwargs)

An output adapter that allows a ChatterBot instance to send responses to a Microsoft bot using Direct Line client protocol.

This is an output adapter that allows a ChatterBot instance to send responses to a Microsoft using Direct Line protocol. Be sure to also see the documentation for the Microsoft input adapter.

```python
bot = ChatBot(
    "My ChatterBot",
    output_adapter="chatterbot.output.Microsoft",
    directline_host="https://directline.botframework.com",
    conversation_id="IEyJvnDULgn",
    direct_line_token_or_secret="RCurR_XV9ZA.cwA.BKA.˓iaJrC8xy8qbOF5xnR2vtCX7Czj01djAPGfiCpg4Fv0",
)
```

4.9.6 Mailgun output adapter

chatterbot.output.Mailgun(**kwargs)

A generic class that can be overridden by a subclass to provide extended functionality, such as delivering a response to an API endpoint.

The Mailgun adapter allows the chat bot to send emails using the Mailgun API.

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot
from settings import MAILGUN

# Change these to match your own email configuration
FROM_EMAIL = "mailgun@salvius.org"
RECIPIENTS = ["gunthercx@gmail.com"]

bot = ChatBot(
    "Mailgun Example Bot",
    mailgun_from_address=FROM_EMAIL,
    mailgun_api_key=MAILGUN["CONSUMER_KEY"],
    mailgun_api_endpoint=MAILGUN["API_ENDPOINT"],
    mailgun_recipients=RECIPIENTS,
    input_adapter="chatterbot.input.Mailgun",
    output_adapter="chatterbot.output.Mailgun",
    storage_adapter="chatterbot.storage.SQLStorageAdapter",
    database_uri="../database.db"
)
```

(continues on next page)
# Send an example email to the address provided
response = bot.get_response("How are you?")
print("Check your inbox at ", RECIPIENTS)

## 4.10 Storage Adapters

Storage adapters provide an interface that allows ChatterBot to connect to different storage backends.

### 4.10.1 Creating a new storage adapter

You can write your own storage adapters by creating a new class that inherits from `StorageAdapter` and overrides necessary methods established in the base `StorageAdapter` class.

```python
class chatterbot.storage.StorageAdapter(base_query=None, *args, **kwargs):
    # This is an abstract class that represents the interface that all storage adapters should implement.

    exception AdapterMethodNotImplementedError
        An exception to be raised when a storage adapter method has not been implemented. Typically this indicates that the method should be implement in a subclass.

    exception EmptyDatabaseException(value='The database currently contains no entries. At least one entry is expected. You may need to train your chat bot to populate your database. ')

    def count():
        # Return the number of entries in the database.

    def create(**kwargs):
        # Creates a new statement matching the keyword arguments specified. Returns the created statement.

    def drop():
        # Drop the database attached to a given adapter.

    def filter(**kwargs):
        # Returns a list of objects from the database. The kwargs parameter can contain any number of attributes. Only objects which contain all listed attributes and in which all values match for all listed attributes will be returned.

    def generate_base_query(chatbot, conversation):
        # Create a base query for the storage adapter.

    def get_model(model_name):
        # Return the model class for a given model name.

    def get_random():
        # Returns a random statement from the database.

    def get_response_statements():
        # Return only statements that are in response to another statement. A statement must exist which lists the closest matching statement in the in_response_to field. Otherwise, the logic adapter may find a closest matching statement that does not have a known response.

        # This method may be overridden by a child class to provide more a efficient method to get these results.

    def remove(statement_text):
        # Removes the statement that matches the input text. Removes any responses from statements where the response text matches the input text.
```
update (statement)
Modifies an entry in the database. Creates an entry if one does not exist.

You will then need to implement the interface established by the StorageAdapter class.

```python
import logging

class StorageAdapter(object):
    
    """This is an abstract class that represents the interface
    that all storage adapters should implement.
    """
    def __init__(self, base_query=None, *args, **kwargs):
        """Initialize common attributes shared by all storage adapters.
        """
        self.kwargs = kwargs
        self.logger = kwargs.get('logger', logging.getLogger(__name__))
        self.adapter_supports_queries = True
        self.base_query = None

def get_model(self, model_name):
    """Return the model class for a given model name.
    """
    # The string must be lowercase
    model_name = model_name.lower()

    kwarg_model_key = '%s_model' % (model_name, )

    if kwarg_model_key in self.kwargs:
        return self.kwargs.get(kwarg_model_key)

    get_model_method = getattr(self, 'get_%s_model' % (model_name, ))
    return get_model_method()

def generate_base_query(self, chatterbot, conversation):
    """Create a base query for the storage adapter.
    """
    if self.adapter_supports_queries:
        for filter_instance in chatterbot.filters:
            self.base_query = filter_instance.filter_selection(chatterbot, conversation)

    def count(self):
        """Return the number of entries in the database.
        """
        raise self.AdapterMethodNotImplementedError(
            'The `count` method is not implemented by this adapter.'
        )

    def remove(self, statement_text):
```

(continues on next page)
```

```
Return only statements that are in response to another statement. A statement must exist which lists the closest matching statement in the `in_response_to` field. Otherwise, the logic adapter may find a closest matching statement that does not have a known response.

This method may be overridden by a child class to provide more an efficient method to get these results.

```python
statement_list = self.filter()
response_statements = set()
statements_for_response_statements = []

for statement in statement_list:
    if statement.in_response_to is not None:
        response_statements.add(statement.in_response_to)

for statement in statement_list:
    if statement.text in response_statements:
        statements_for_response_statements.append(statement)

return statements_for_response_statements
```

```python
class EmptyDatabaseException(Exception):
    def __init__(self, value='The database currently contains no entries. At least one entry is expected. You may need to train your chat bot to populate your database. '):
        self.value = value
    def __str__(self):
        return repr(self.value)

class AdapterMethodNotImplementedError(NotImplementedError):
    def __init__(self):
        self.value = 'An exception to be raised when a storage adapter method has not been implemented. Typically this indicates that the method should be implement in a subclass.'
    def __str__(self):
        return self.value
```

The storage adapter that your bot uses can be specified by setting the `storage_adapter` parameter to the import path of the storage adapter you want to use.

```python
chatbot = ChatBot(
    "My ChatterBot",
    storage_adapter="chatterbot.storage.SQLStorageAdapter"
)
```

### 4.10.2 SQL Storage Adapter

```python
class chatterbot.storage.SQLStorageAdapter(**kwargs)
```

SQLStorageAdapter allows ChatterBot to store conversation data semi-structured T-SQL database, virtually, any database that SQL Alchemy supports.

**Notes:** Tables may change (and will), so, save your training data. There is no data migration (yet). Performance test not done yet. Tests using other databases not finished.
All parameters are optional, by default a sqlite database is used.

It will check if tables are present, if they are not, it will attempt to create the required tables.

Parameters

• **database_uri** (str) – eg: sqlite:///database_test.db", use database_uri or database, database_uri can be specified to choose database driver (database parameter will be ignored).

• **read_only** (bool) – False by default, makes all operations read only, has priority over all DB operations so, create, update, delete will NOT be executed

count()
   Return the number of entries in the database.

create(**kwargs)
   Creates a new statement matching the keyword arguments specified. Returns the created statement.

create_database()
   Populate the database with the tables.

drop()
   Drop the database attached to a given adapter.

filter(**kwargs)
   Returns a list of objects from the database. The kwargs parameter can contain any number of attributes. Only objects which contain all listed attributes and in which all values match for all listed attributes will be returned.

get_random()
   Returns a random statement from the database.

get_statement_model()
   Return the statement model.

get_tag_model()
   Return the conversation model.

remove(statement_text)
   Removes the statement that matches the input text. Removes any responses from statements where the response text matches the input text.

update(statement)
   Modifies an entry in the database. Creates an entry if one does not exist.

4.10.3 MongoDB Storage Adapter

class chatterbot.storage.MongoDatabaseAdapter(**kwargs)
   The MongoDatabaseAdapter is an interface that allows ChatterBot to store statements in a MongoDB database.

   Parameters **database_uri** (str) – The URI of a remote instance of MongoDB. This can be any valid MongoDB connection string

   ```
database_uri='mongodb://example.com:8100/'
```

count()
   Return the number of entries in the database.

create(**kwargs)
   Creates a new statement matching the keyword arguments specified. Returns the created statement.
drop ()
    Remove the database.

filter (**kwargs)
    Returns a list of statements in the database that match the parameters specified.

get_random ()
    Returns a random statement from the database

get_response_statements ()
    Return only statements that are in response to another statement. A statement must exist which lists the closest matching statement in the in_response_to field. Otherwise, the logic adapter may find a closest matching statement that does not have a known response.

get_statement_model ()
    Return the class for the statement model.

mongo_to_object (statement_data)
    Return Statement object when given data returned from Mongo DB.

remove (statement_text)
    Removes the statement that matches the input text.

update (statement)
    Modifies an entry in the database. Creates an entry if one does not exist.

4.11 Filters

Filters are an efficient way to create base queries that can be passed to ChatterBot’s storage adapters. Filters will reduce the number of statements that a chat bot has to process when it is selecting a response.

4.11.1 How to create a new filter for ChatterBot

This is the basic outline of the code that your filter will need to follow. Each filter should inherit from ChatterBot’s Filter class and implement a method called filter_selection. Everything else that your filter does is up to you.

```python
from chatterbot.filters import Filter

class MyFilter(Filter):
    def filter_selection(self, chatterbot):
        # ...
        return query
```

4.11.1.1 Filter Queries

Filters use a storage adapter’s query object to build a query that the adapter can evaluate. The available query methods currently are:

statement_text_not_in(statements)

This query method takes a list of statement text values and returns the current query with the added constraint that any statements returned cannot exist in the list specified.
statement_response_list_contains(statement_text)

This query method takes a single statement text value and returns the current query with the added constraint that any statements returned must contain the specified text as a response.

statement_response_list_equals(response_list)

This query method takes a list of statement text values and returns the current query with the added constraint that any statements returned must have an exactly matching list of response values.

4.11.1.2 Filter Support

Not all storage adapters support filters. If a storage adapter does not support filters, then queries generated by filters will be ignored when using that storage adapter.

A storage adapter only supports filters if it supports querying. You can tell if a storage adapter supports querying by checking if its adapter_supports_queries property is set to true.

4.11.2 Setting filters

```python
chatbot = ChatBot(
    "My ChatterBot",
    filters=["chatterbot.filters.RepetitiveResponseFilter"]
)
```

4.11.3 Filter classes

class chatterbot.filters.RepetitiveResponseFilter

A filter that eliminates possibly repetitive responses to prevent a chat bot from repeating statements that it has recently said.

filter_selection(chatterbot, conversation)

Because this is the base filter class, this method just returns the storage adapter’s base query. Other filters are expected to override this method.

4.12 ChatterBot

The main class ChatBot is a connecting point between each of ChatterBot’s adapters. In this class, an input statement is returned from the input adapter, processed and stored by the logic adapter and storage adapter, and then passed to the output adapter to be returned to the user.

class chatterbot.ChatBot(name, **kwargs)

A conversational dialog chat bot.

Parameters

- name (str) – A name is the only required parameter for the ChatBot class.
- storage_adapter (str) – The dot-notated import path to a storage adapter class. Defaults to "chatterbot.storage.SQLStorageAdapter".
• **logic_adapters (list)** – A list of dot-notated import paths to each logic adapter the bot uses. Defaults to "chatterbot.logic.BestMatch".

• **input_adapter (str)** – The dot-notated import path to an input adapter class. Defaults to "chatterbot.input.VariableInputTypeAdapter".

• **output_adapter (str)** – The dot-notated import path to an output adapter class. Defaults to "chatterbot.output.OutputAdapter".

• **filters (list)** – A list of dot-notated import paths to filter classes to be used by the chatbot.

• **logger (logging.Logger)** – A Logger object.

**generate_response (input_statement)**
Return a response based on a given input statement.

Parameters **input_statement** – The input statement to be processed.

**get_latest_response (conversation)**
Returns the latest response in a conversation if it exists. Returns None if a matching conversation cannot be found.

**get_logic_adapters ()**
Return a list of all logic adapters being used, including system logic adapters.

**get_response (input_item)**
Return the bot's response based on the input.

Parameters **input_item** – An input value.

Returns A response to the input.

Return type **Statement**

**initialize ()**
Do any work that needs to be done before the responses can be returned.

**learn_response (statement, previous_statement)**
Learn that the statement provided is a valid response.

### 4.12.1 Example chat bot parameters

```python
ChatBot(
    'Northumberland',
    storage_adapter='my.storage.AdapterClass',
    logic_adapters=[
        'my.logic.AdapterClass1',
        'my.logic.AdapterClass2'
    ],
    input_adapter='my.input.AdapterClass',
    output_adapter='my.output.AdapterClass',
    filters=[
        'my.filter.FilterClass1',
        'my.filter.FilterClass2'
    ],
    logger=custom_logger
)
```
### 4.12.2 Example expanded chat bot parameters

It is also possible to pass parameters directly to individual adapters. To do this, you must use a dictionary that contains a key called `import_path` which specifies the import path to the adapter class.

```python
ChatBot(
    'Leander Jenkins',
    storage_adapter={
        'import_path': 'my.storage.AdapterClass',
        'database_uri': 'protocol://my-database'
    },
    logic_adapters=[
        {
            'import_path': 'my.logic.AdapterClass1',
            'statement_comparison_function': 'chatterbot.comparisons.levenshtein_distance',
            'response_selection_method': 'chatterbot.response_selection.get_first_response'
        },
        {
            'import_path': 'my.logic.AdapterClass2',
            'statement_comparison_function': 'my.custom.comparison_function'
            'response_selection_method': 'my.custom.selection_method'
        }
    ],
    input_adapter={
        'import_path': 'my.input.AdapterClass',
        'api_key': '0000-1111-2222-3333-DDDD'
    },
    output_adapter={
        'import_path': 'my.output.AdapterClass',
        'api_key': '0000-1111-2222-3333-DDDD'
    }
)
```

### 4.12.3 Enable logging

ChatterBot has built in logging. You can enable ChatterBot’s logging by setting the logging level in your code.

```python
import logging
logging.basicConfig(level=logging.INFO)
ChatBot(
    # ...
)
```

The logging levels available are CRITICAL, ERROR, WARNING, INFO, DEBUG, and NOTSET. See the Python logging documentation for more information.

### 4.12.4 Using a custom logger

You can choose to use your own custom logging class with your chat bot. This can be useful when testing and debugging your code.
import logging

custom_logger = logging.getLogger(__name__)

ChatBot(
    # ...
    logger=custom_logger
)

4.12.5 Adapters

ChatterBot uses adapter modules to control the behavior of specific types of tasks. There are four distinct types of adapters that ChatterBot uses, these are storage adapters, input adapters, output adapters and logic adapters.

4.12.5.1 Adapters types

1. Storage adapters - Provide an interface for ChatterBot to connect to various storage systems such as MongoDB or local file storage.
2. Input adapters - Provide methods that allow ChatterBot to get input from a defined data source.
3. Output adapters - Provide methods that allow ChatterBot to return a response to a defined data source.
4. Logic adapters - Define the logic that ChatterBot uses to respond to input it receives.

4.12.5.2 Accessing the chatbot instance

When ChatterBot initializes each adapter, it sets an attribute named chatbot. The chatbot variable makes it possible for each adapter to have access to all of the other adapters being used. Suppose two input and output adapters need to share some information or perhaps you want to give your logic adapter direct access to the storage adapter. These are just a few cases where this functionality is useful.

Each adapter can be accessed on the chatbot object from within an adapter by referencing self.chatbot. Then, self.chatbot.storage refers to the storage adapter, self.chatbot.input refers to the input adapter, self.chatbot.output refers to the current output adapter, and self.chatbot.logic refers to the logic adapters.

4.13 Conversations

ChatterBot supports the ability to have multiple concurrent conversations. A conversations is where the chat bot interacts with a person, and supporting multiple concurrent conversations means that the chat bot can have multiple different conversations with different people at the same time.

4.13.1 Conversation scope

If two ChatBot instances are created, each will have conversations separate from each other.

An adapter can access any conversation as long as the unique identifier for the conversation is provided.
4.13.2 Conversation example

The following example is taken from the Django ChatterBotApiView built into ChatterBot. In this method, the unique identifiers for each chat session are being stored in Django’s session objects. This allows different users who interact with the bot through different web browsers to have separate conversations with the chat bot.

```python
def post(self, request, *args, **kwargs):
    """
    Return a response to the statement in the posted data.
    """
    input_data = json.loads(request.read().decode('utf-8'))

    if 'text' not in input_data:
        return JsonResponse({'text': ['The attribute "text" is required.']}, status=400)

    response = self.chatterbot.get_response(input_data)
    response_data = response.serialize()

    return JsonResponse(response_data, status=200)
```

4.13.2.1 Statements

ChatterBot’s statement objects represent either an input statement that the chat bot has received from a user, or an output statement that the chat bot has returned based on some input.

```python
class chatterbot.conversation.Statement(text, **kwargs)
    A statement represents a single spoken entity, sentence or phrase that someone can say.

    confidence = None
    ChatterBot's logic adapters assign a confidence score to the statement before it is returned. The confidence score indicates the degree of certainty with which the chat bot believes this is the correct response to the given input.

    in_response_to = None
    The response attribute represents the relationship between two statements. This value of this field indicates that one statement was issued in response to another statement.

    exception InvalidTypeException (value='Received an unexpected value type.')</n
    save()
    Save the statement in the database.
```

4.13.2.2 Statement-response relationship

ChatterBot stores knowledge of conversations as statements. Each statement can have any number of possible responses.
Each `Statement` object has an `in_response_to` reference which links the statement to a number of other statements that it has been learned to be in response to. The `in_response_to` attribute is essentially a reference to all parent statements of the current statement.

The count of recorded statements with matching, or similar text indicates the number of times that the statement has been given as a response. This makes it possible for the chat bot to determine if a particular response is more commonly used than another.

### 4.14 Comparisons

#### 4.14.1 Statement comparison

ChatterBot uses `Statement` objects to hold information about things that can be said. An important part of how a chat bot selects a response is based on its ability to compare two statements to each other. There are a number of ways to do this, and ChatterBot comes with a handful of methods built in for you to use.

This module contains various text-comparison algorithms designed to compare one statement to another.

```python
class chatterbot.comparisons.JaccardSimilarity
    Calculates the similarity of two statements based on the Jaccard index.

    The Jaccard index is composed of a numerator and denominator. In the numerator, we count the number of items
    that are shared between the sets. In the denominator, we count the total number of items across both sets. Let’s
    say we define sentences to be equivalent if 50% or more of their tokens are equivalent. Here are two sample
    sentences:

        The young cat is hungry. The cat is very hungry.

    When we parse these sentences to remove stopwords, we end up with the following two sets:

        {young, cat, hungry} {cat, very, hungry}

    In our example above, our intersection is {cat, hungry}, which has count of two. The union of the sets is {young,
    cat, very, hungry}, which has a count of four. Therefore, our Jaccard similarity index is two divided by four, or
    50%. Given our similarity threshold above, we would consider this to be a match.

    compare(statement, other_statement)
        Return the calculated similarity of two statements based on the Jaccard index.

    initialize_nltk_wordnet()
        Download the NLTK wordnet corpora that is required for this algorithm to run only if the corpora has not
        already been downloaded.

class chatterbot.comparisons.LevenshteinDistance
    Compare two statements based on the Levenshtein distance of each statement’s text.

    For example, there is a 65% similarity between the statements “where is the post office?” and “looking for the
    post office” based on the Levenshtein distance algorithm.

    compare(statement, other_statement)
        Compare the two input statements.

        Returns The percent of similarity between the text of the statements.

        Return type float
```
class chatterbot.comparisons.SentimentComparison
    Calculate the similarity of two statements based on the closeness of the sentiment value calculated for each
    statement.

    compare(statement, other_statement)
    Return the similarity of two statements based on their calculated sentiment values.

    Returns The percent of similarity between the sentiment value.
    Return type float

initialize_nltk_vader_lexicon()
    Download the NLTK vader lexicon for sentiment analysis that is required for this algorithm to run.

class chatterbot.comparisons.SynsetDistance
    Calculate the similarity of two statements. This is based on the total maximum synset similarity between each
    word in each sentence.

    This algorithm uses the wordnet functionality of NLTK to determine the similarity of two statements based on
    the path similarity between each token of each statement. This is essentially an evaluation of the closeness of
    synonyms.

    compare(statement, other_statement)
    Compare the two input statements.

    Returns The percent of similarity between the closest synset distance.
    Return type float

initialize_nltk_punkt()
    Download required NLTK corpora if they have not already been downloaded.

initialize_nltk_stopwords()
    Download required NLTK corpora if they have not already been downloaded.

initialize_nltk_wordnet()
    Download required NLTK corpora if they have not already been downloaded.

4.14.1.1 Use your own comparison function

You can create your own comparison function and use it as long as the function takes two statements as parameters and
returns a numeric value between 0 and 1. A 0 should represent the lowest possible similarity and a 1 should represent
the highest possible similarity.

    def comparison_function(statement, other_statement):
        # Your comparison logic
        # Return your calculated value here
        return 0.0

Setting the comparison method

To set the statement comparison method for your chat bot, you will need to pass the statement_comparison_function parameter to your chat bot when you initialize it. An example of this is shown below.
from chatterbot import ChatBot
from chatterbot.comparisons import levenshtein_distance

chatbot = ChatBot(
    
)

4.15 Utility Methods

ChatterBot has a utility module that contains a collection of miscellaneous but useful functions.

4.15.1 Module imports

chatterbot.utils.import_module(dotted_path)
Imports the specified module based on the dot notated import path for the module.

4.15.2 Class initialization

chatterbot.utils.initialize_class(data, **kwargs)
Parameters data – A string or dictionary containing a import_path attribute.

NLTK corpus downloader

chatterbot.utils.nltk_download_corpus(resource_path)
Download the specified NLTK corpus file unless it has already been downloaded.

Returns True if the corpus needed to be downloaded.

4.15.3 Stopword removal

chatterbot.utils.remove_stopwords(tokens, language)
Takes a language (i.e. ‘english’), and a set of word tokens. Returns the tokenized text with any stopwords removed. Stop words are words like “is, the, a, . . .”

Be sure to download the required NLTK corpus before calling this function: - from chatterbot.utils import nltk_download_corpus - nltk_download_corpus(‘corpora/stopwords’)

4.15.4 ChatBot response time

chatterbot.utils.get_response_time(chatbot)
Returns the amount of time taken for a given chat bot to return a response.

Parameters chatbot (ChatBot) – A chat bot instance.

Returns The response time in seconds.

Return type float
4.15.5 Parsing datetime information

chatterbot.parsing.datetime_parsing(text, base_date=datetime.datetime(2018, 9, 26, 1, 53, 26, 395882))

Extract datetime objects from a string of text.

4.16 ChatterBot Corpus

This is a corpus of dialog data that is included in the chatterbot module.

Additional information about the chatterbot-corpus module can be found in the ChatterBot Corpus Documentation.

4.16.1 Corpus language availability

Corpus data is user contributed, but it is also not difficult to create one if you are familiar with the language. This is because each corpus is just a sample of various input statements and their responses for the bot to train itself with.

To explore what languages and collections of corpora are available, check out the chatterbot_corpus/data directory in the separate chatterbot-corpus repository.

Note: If you are interested in contributing content to the corpus, please feel free to submit a pull request on ChatterBot’s corpus GitHub page. Contributions are welcomed!

https://github.com/gunthercox/chatterbot-corpus

The chatterbot-corpus is distributed in its own Python package so that it can be released and upgraded independently from the chatterbot package.

4.16.2 Exporting your chat bot’s database as a training corpus

Now that you have created your chat bot and sent it out into the world, perhaps you are looking for a way to share what it has learned with other chat bots? ChatterBot’s training module provides methods that allow you to export the content of your chat bot’s database as a training corpus that can be used to train other chat bots.

```python
chatbot = ChatBot('Export Example Bot')
chatbot.trainer.export_for_training('./export.yml')
```

Here is an example:

```python
# -*- coding: utf-8 -*-
from chatterbot import ChatBot
from chatterbot.trainers import ChatterBotCorpusTrainer

''''
This is an example showing how to create an export file from an existing chat bot that can then be used to train other bots.
''''

chatbot = ChatBot('Export Example Bot')

# First, lets train our bot with some data
```

(continues on next page)
4.17 Django Integration

ChatterBot has direct support for integration with Django’s ORM. It is relatively easy to use ChatterBot within your Django application to create conversational pages and endpoints.

4.17.1 Chatterbot Django Settings

You can edit the ChatterBot configuration through your Django settings.py file.

```python
CHATTERBOT = {
    'name': 'Tech Support Bot',
    'logic_adapters': [
        'chatterbot.logic.MathematicalEvaluation',
        'chatterbot.logic.TimeLogicAdapter',
        'chatterbot.logic.BestMatch'
    ]
}
```

Any setting that gets set in the CHATTERBOT dictionary will be passed to the chat bot that powers your django app.

4.17.1.1 Additional Django settings

- `django_app_name` [default: ‘django_chatterbot’] The Django app name to look up the models from.

4.17.2 ChatterBot Django Views

4.17.2.1 Example API Views

ChatterBot’s Django example comes with an API view that demonstrates one way to use ChatterBot to create a conversational API endpoint for your application.

The endpoint expects a JSON request in the following format:

```json
{"text": "My input statement"}
```

```python
class ChatterBotApiView(View):
    
    # Provide an API endpoint to interact with ChatterBot.
    
    chatterbot = ChatBot(**settings.CHATTERBOT)

    def post(self, request, *args, **kwargs):
```

(continues on next page)
"""
Return a response to the statement in the posted data.
"""
* The JSON data should contain a 'text' attribute.
"""
input_data = json.loads(request.read().decode('utf-8'))

if 'text' not in input_data:
    return JsonResponse({'
        'text': [
            'The attribute "text" is required.'
        ]
    }, status=400)

response = self.chatterbot.get_response(input_data)
response_data = response.serialize()

return JsonResponse(response_data, status=200)

def get(self, request, *args, **kwargs):
    """
    Return data corresponding to the current conversation.
    """
    return JsonResponse({'
        'name': self.chatterbot.name
    })

Note: Looking for the full example? Check it out on GitHub: https://github.com/gunthercox/ChatterBot/tree/master/examples/django_app

4.17.3 Webservices

If you want to host your Django app, you need to choose a method through which it will be hosted. There are a few free services that you can use to do this such as Heroku and PythonAnywhere.

4.17.3.1 WSGI

A common method for serving Python web applications involves using a Web Server Gateway Interface (WSGI) package.

Gunicorn is a great choice for a WSGI server. They have detailed documentation and installation instructions on their website.

4.17.3.2 Hosting static files

There are numerous ways to host static files for your Django application. One extremely easy way to do this is by using WhiteNoise, a python package designed to make it possible to serve static files from just about any web application.
4.17.4 Install packages

Begin by making sure that you have installed both `django` and `chatterbot`.

```
pip install django chatterbot
```

For more details on installing Django, see the Django documentation.

4.17.4.1 Installed Apps

Add `chatterbot.ext.django_chatterbot` to your `INSTALLED_APPS`

```
INSTALLED_APPS = (  
    # ...  
    'chatterbot.ext.django_chatterbot',  
)
```

4.17.4.2 Migrations

You can run the Django database migrations for your chat bot with the following command.

```
python manage.py migrate django_chatterbot
```

4.17.4.3 MongoDB and Django

ChatterBot has a storage adapter for MongoDB but it does not work with Django. If you want to use MongoDB as your database for Django and your chat bot then you will need to install a Django storage backend such as Django MongoDB Engine.

The reason this is required is because Django’s storage backends are different and completely separate from ChatterBot’s storage adapters.

4.18 Frequently Asked Questions

This document is comprised of questions that are frequently asked about ChatterBot and chat bots in general.

4.18.1 Python String Encoding

The Python developer community has published a great article that covers the details of unicode character processing.

- Python 3: https://docs.python.org/3/howto/unicode.html
- Python 2: https://docs.python.org/2/howto/unicode.html

The following notes are intended to help answer some common questions and issues that developers frequently encounter while learning to properly work with different character encodings in Python.
4.18.1.1 Does ChatterBot handle non-ascii characters?

ChatterBot is able to handle unicode values correctly. You can pass to it non-encoded data and it should be able to process it properly (you will need to make sure that you decode the output that is returned).

Below is one of ChatterBot’s tests from tests/test_chatbot.py, this is just a simple check that a unicode response can be processed.

```python
def test_get_response_unicode(self):
    """
    Test the case that a unicode string is passed in.
    """
    response = self.chatbot.get_response(u'')
    self.assertGreater(len(response.text), 0)
```

This test passes in both Python 2.7 and 3.x. It also verifies that ChatterBot can take unicode input without issue.

4.18.1.2 How do I fix Python encoding errors?

When working with string type data in Python, it is possible to encounter errors such as the following.

```
UnicodeDecodeError: 'utf8' codec can't decode byte 0x92 in position 48: invalid start-byte
```

Depending on what your code looks like, there are a few things that you can do to prevent errors like this.

**Unicode header**

```python
# -*- coding: utf-8 -*-
```

**When to use the unicode header**

If your strings use escaped unicode characters (they look like `u'\u00b0C'`) then you do not need to add the header. If you use strings like `ØÆÅ` then you are required to use the header.

If you are using this header it must be the first line in your Python file.

**Unicode escape characters**

```python
>>> print u'\u0420\u043e\u0441\u0441\u0438\u044f'
```

**When to use escape characters**

Prefix your strings with the unicode escape character `u'...'` when you are using escaped unicode characters.
Import unicode literals from future

```
from __future__ import unicode_literals
```

When to import unicode literals

Use this when you need to make sure that Python 3 code also works in Python 2.
A good article on this can be found here: http://python-future.org/unicode_literals.html

4.18.2 How do I deploy my chat bot to the web?

There are a number of excellent web frameworks for creating Python projects out there. Django and Flask are two excellent examples of these. ChatterBot is designed to be agnostic to the platform it is deployed on and it is very easy to get set up.

To run ChatterBot inside of a web application you just need a way for your application to receive incoming data and to return data. You can do this any way you want, HTTP requests, web sockets, etc.

There are a number of existing examples that show how to do this.

1. An example using Django: https://github.com/gunthercox/ChatterBot/tree/master/examples/django_app

Additional details and recommendations for configuring Django can be found in the Webservices section of ChatterBot’s Django documentation.

4.18.3 What kinds of machine learning does ChatterBot use?

In brief, ChatterBot uses a number of different machine learning techniques to generate its responses. The specific algorithms depend on how the chat bot is used and the settings that it is configured with.

Here is a general overview of some of the various machine learning techniques that are employed throughout ChatterBot’s codebase.

4.18.3.1 1. Search algorithms

Searching is the most rudimentary form of artificial intelligence. To be fair, there are differences between machine learning and artificial intelligence but lets avoid those for now and instead focus on the topic of algorithms that make the chat bot talk intelligently.

Search is a crucial part of how a chat bot quickly and efficiently retrieves the possible candidate statements that it can respond with.

Some examples of attributes that help the chat bot select a response include

- the similarity of an input statement to known statements
- the frequency in which similar known responses occur
- the likeliness of an input statement to fit into a category that known statements are a part of
Several logic adapters in ChatterBot use naive Bayesian classification algorithms to determine if an input statement meets a particular set of criteria that warrant a response to be generated from that logic adapter.

### 4.19 Command line tools

ChatterBot comes with a few command line tools that can help

#### 4.19.1 Get the installed ChatterBot version

If you have ChatterBot installed and you want to check what version you have then you can run the following command.

```bash
python -m chatterbot --version
```

#### 4.19.2 Locate NLTK data

ChatterBot uses the Natural Language Toolkit (NLTK) for various language processing functions. ChatterBot downloads additional data that is required by NLTK. The following command can be used to find all NLTK data directories that contain files.

```bash
python -m chatterbot list_nltk_data
```

### 4.20 Development

As the code for ChatterBot is written, the developers attempt to describe the logic and reasoning for the various decisions that go into creating the internal structure of the software. This internal documentation is intended for future developers and maintainers of the project. A majority of this information is unnecessary for the typical developer using ChatterBot.

It is not always possible for every idea to be documented. As a result, the need may arise to question the developers and maintainers of this project in order to pull concepts from their minds and place them in these documents. Please pull gently.

#### 4.20.1 Contributing to ChatterBot

There are numerous ways to contribute to ChatterBot. All of which are highly encouraged.

- Contributing bug reports and feature requests
- Contributing documentation
- Contributing code for new features
- Contributing fixes for bugs

Every bit of help received on this project is highly appreciated.
4.20.1.1 Setting Up a Development Environment

To contribute to ChatterBot’s development, you simply need:

- Python
- pip
- A few python packages:
  
  ```
  pip install requirements.txt
  pip install dev-requirements.txt
  ```
- A text editor

4.20.1.2 Reporting a Bug

If you discover a bug in ChatterBot and wish to report it, please be sure that you adhere to the following when you report it on GitHub.

1. Before creating a new bug report, please search to see if an open or closed report matching yours already exists.
2. Please include a description that will allow others to recreate the problem you encountered.

4.20.1.3 Requesting New Features

When requesting a new feature in ChatterBot, please make sure to include the following details in your request.

1. Your use case. Describe what you are doing that requires this new functionality.

4.20.1.4 Contributing Documentation

ChatterBot’s documentation is written in reStructuredText and is compiled by Sphinx. The reStructuredText source of the documentation is located in `docs/`.

To build the documentation yourself, run:

```
sphinx-build ./docs/ ./build/
```

You can then open the index.html file that will be created in the build directory.

4.20.1.5 Contributing Code

The development of ChatterBot happens on GitHub. Code contributions should be submitted there in the form of pull requests.

Pull requests should meet the following criteria.

1. Fix one issue and fix it well.
2. Do not include extraneous changes that do not relate to the issue being fixed.
3. Include a descriptive title and description for the pull request.
4. Have descriptive commit messages.
4.20.2 Releasing ChatterBot

ChatterBot follows the following rules when it comes to new versions and updates.

4.20.2.1 Versioning

ChatterBot follows semantic versioning as a set of guidelines for release versions.

- **Major** releases (2.0.0, 3.0.0, etc.) are used for large, almost entirely backwards incompatible changes.
- **Minor** releases (2.1.0, 2.2.0, 3.1.0, 3.2.0, etc.) are used for releases that contain small, backwards incompatible changes. Known backwards incompatibilities will be described in the release notes.
- **Patch** releases (e.g., 2.1.1, 2.1.2, 3.0.1, 3.0.10, etc.) are used for releases that contain bug fixes, features and dependency changes.

4.20.2.2 Release Process

The following procedure is used to finalize a new version of ChatterBot.

1. We make sure that all CI tests on the master branch are passing.
2. We tag the release on GitHub.
3. A new package is generated from the latest version of the master branch.

   ```python
   python setup.py sdist bdist_wheel
   ```

4. The Python package files are uploaded to PyPi.

   ```
   twine upload dist/*
   ```

4.20.3 Unit Testing

“A true professional does not waste the time and money of other people by handing over software that is not reasonably free of obvious bugs; that has not undergone minimal unit testing; that does not meet the specifications and requirements; that is gold-plated with unnecessary features; or that looks like junk.” – Daniel Read

4.20.3.1 ChatterBot tests

ChatterBot’s built in tests can be run using nose. See the nose documentation for more information.

   ```
   nosetests
   ```

   *Note* that nose also allows you to specify individual test cases to run. For example, the following command will run all tests in the test-module `tests/logic_adapter_tests`

   ```
   nosetests tests/logic_adapter_tests
   ```
4.20.3.2 Django integration tests

Tests for Django integration have been included in the tests_django directory and can be run with:

```
python runtests.py
```

4.20.3.3 Django example app tests

Tests for the example Django app can be run with the following command from within the examples/django_app directory.

```
python manage.py test
```

4.20.3.4 Benchmark tests

You can run a series of benchmark tests that test a variety of different chat bot configurations for performance by running the following command.

```
python tests/benchmarks.py
```

4.20.3.5 Running all the tests

You can run all of ChatterBot’s tests with a single command: tox.

Tox is a tool for managing virtual environments and running tests.

Installing tox

You can install tox with pip.

```
pip install tox
```

Using tox

When you run the tox command from within the root directory of the ChatterBot repository it will run the following tests:

1. Tests for ChatterBot’s core files.
2. Tests for ChatterBot’s integration with multiple versions of Django.
3. Tests for each of ChatterBot’s example files.
5. Code style and validation checks (linting).

You can run specific tox environments using the -e flag. A few examples include:

```
# Run the documentation tests
tox -e docs
```
# Run the tests with Django 2.0
```
tox -e django20
```

# Run the code linting scripts
```
tox -e lint
```

To see the list of all available environments that you can run tests for:
```
tox -l
```

To run tests for all environments:
```
tox
```

## 4.20.4 Packaging your code for ChatterBot

There are cases where developers may want to contribute code to ChatterBot but for various reasons it doesn’t make sense or isn’t possible to add the code to the main ChatterBot repository on GitHub. Common reasons that code can’t be contributed include:

- **Licencing**: It may not be possible to contribute code to ChatterBot due to a licencing restriction or a copyright.
- **Demand**: There needs to be a general demand from the open source community for a particular feature so that there are developers who will want to fix and improve the feature if it requires maintenance.

In addition, all code should be well documented and thoroughly tested.

### 4.20.4.1 Package directory structure

Suppose we want to create a new logic adapter for ChatterBot and add it the Python Package Index (PyPI) so that other developers can install it and use it. We would begin doing this by setting up a directory file the following structure.

```bash
Listing 1: Python Module Structure

IronyAdapter/  
|-- README
|-- setup.py
|-- irony_adapter
|  |-- __init__.py
|  |-- logic.py
|-- tests
|  |-- __init__.py
|  |-- test_logic.py
```

More information on creating Python packages can be found here: [https://packaging.python.org/tutorials/distributing-packages/](https://packaging.python.org/tutorials/distributing-packages/)

### Register on PyPI

Create an account: [https://pypi.python.org/pypi?%3Aaction=register_form](https://pypi.python.org/pypi?%3Aaction=register_form)

Create a `.pypirc` configuration file.
Listing 2: .pypirc file contents

```
[distutils]
index-servers =
pypi

[pypi]
username=my_username
password=my_password
```

Generate packages

```
python setup.py sdist bdist_wheel
```

Upload packages

The official tool for uploading Python packages is called twine. You can install twine with pip if you don’t already have it installed.

```
pip install twine
twine upload dist/*
```

Install your package locally

```
cd IronyAdapter
pip install . --upgrade
```

Using your package

If you are creating a module that ChatterBot imports from a dotted module path then you can set the following in your chat bot.

```
chatbot = ChatBot(
    "My ChatBot",
    logic_adapters=[
        "irony_adapter.logic.IronyAdapter"
    ]
)
```

Testing your code

```
from unittest import TestCase

class IronyAdapterTestCase(TestCase):

```
Test that the irony adapter allows the chat bot to understand irony.

def test_irony(self):
    # TODO: Implement test logic
    self.assertTrue(response.irony)

4.21 Glossary

adapters  A pluggable class that allows a ChatBot instance to execute some kind of functionality.

logic adapter  An adapter class that allows a ChatBot instance to select a response to

storage adapter  A class that allows a chat bot to store information somewhere, such as a database.

input adapter  An adapter class that gets input from somewhere and provides it to the chat bot.

output adapter  An adapter class that returns a chat bot’s response.

corpus  In linguistics, a corpus (plural corpora) or text corpus is a large and structured set of texts. They are used to do statistical analysis and hypothesis testing, checking occurrences or validating linguistic rules within a specific language territory\(^1\).

preprocessors  A member of a list of functions that can be used to modify text input that the chat bot receives before the text is passed to the logic adapter for processing.

statement  A single string of text representing something that can be said.

response  A single string of text that is uttered as an answer, a reply or an acknowledgement to a statement.

untrained instance  An untrained instance of the chat bot has an empty database.

\(^1\) https://en.wikipedia.org/wiki/Text_corpus
Report an Issue

Please direct all bug reports and feature requests to the project’s issue tracker on GitHub.
