
Cryptography Documentation

Release 2.0.dev1

Individual Contributors

Jun 23, 2017

1	Installation	3
2	Layout	5
2.1	Fernet (symmetric encryption)	5
2.2	X.509	8
2.3	Primitives	45
2.4	Exceptions	118
2.5	Random number generation	118
2.6	Backends	119
2.7	Bindings	130
2.8	Installation	131
2.9	Changelog	135
2.10	Frequently asked questions	148
2.11	Development	149
2.12	Security	191
2.13	Known security limitations	193
2.14	API stability	193
2.15	Doing a release	194
2.16	Community	196
2.17	Glossary	196
	Python Module Index	199

cryptography includes both high level recipes and low level interfaces to common cryptographic algorithms such as symmetric ciphers, message digests, and key derivation functions. For example, to encrypt something with cryptography's high level symmetric encryption recipe:

```
>>> from cryptography.fernet import Fernet
>>> # Put this somewhere safe!
>>> key = Fernet.generate_key()
>>> f = Fernet(key)
>>> token = f.encrypt(b"A really secret message. Not for prying eyes.")
>>> token
'...'
>>> f.decrypt(token)
'A really secret message. Not for prying eyes.'
```

If you are interested in learning more about the field of cryptography, we recommend [Crypto 101](#), by Laurens Van Houtven.

CHAPTER 1

Installation

You can install `cryptography` with `pip`:

```
$ pip install cryptography
```

See *Installation* for more information.

cryptography is broadly divided into two levels. One with safe cryptographic recipes that require little to no configuration choices. These are safe and easy to use and don't require developers to make many decisions.

The other level is low-level cryptographic primitives. These are often dangerous and can be used incorrectly. They require making decisions and having an in-depth knowledge of the cryptographic concepts at work. Because of the potential danger in working at this level, this is referred to as the “hazardous materials” or “hazmat” layer. These live in the `cryptography.hazmat` package, and their documentation will always contain an admonition at the top.

We recommend using the recipes layer whenever possible, and falling back to the hazmat layer only when necessary.

Fernet (symmetric encryption)

Fernet guarantees that a message encrypted using it cannot be manipulated or read without the key. `Fernet` is an implementation of symmetric (also known as “secret key”) authenticated cryptography. Fernet also has support for implementing key rotation via `MultiFernet`.

class `cryptography.fernet.Fernet` (*key*)

This class provides both encryption and decryption facilities.

```
>>> from cryptography.fernet import Fernet
>>> key = Fernet.generate_key()
>>> f = Fernet(key)
>>> token = f.encrypt(b"my deep dark secret")
>>> token
'...'
>>> f.decrypt(token)
'my deep dark secret'
```

Parameters *key* (*bytes*) – A URL-safe base64-encoded 32-byte key. This **must** be kept secret. Anyone with this key is able to create and read messages.

classmethod `generate_key()`

Generates a fresh fernet key. Keep this some place safe! If you lose it you'll no longer be able to decrypt messages; if anyone else gains access to it, they'll be able to decrypt all of your messages, and they'll also be able forge arbitrary messages that will be authenticated and decrypted.

encrypt (*data*)

Parameters *data* (*bytes*) – The message you would like to encrypt.

Returns bytes A secure message that cannot be read or altered without the key. It is URL-safe base64-encoded. This is referred to as a “Fernet token”.

Raises `TypeError` – This exception is raised if *data* is not *bytes*.

Note: The encrypted message contains the current time when it was generated in *plaintext*, the time a message was created will therefore be visible to a possible attacker.

decrypt (*token*, *t1=None*)**Parameters**

- **token** (*bytes*) – The Fernet token. This is the result of calling `encrypt()`.
- **t1** (*int*) – Optionally, the number of seconds old a message may be for it to be valid. If the message is older than *t1* seconds (from the time it was originally created) an exception will be raised. If *t1* is not provided (or is `None`), the age of the message is not considered.

Returns bytes The original plaintext.

Raises

- `cryptology.fernet.InvalidToken` – If the *token* is in any way invalid, this exception is raised. A token may be invalid for a number of reasons: it is older than the *t1*, it is malformed, or it does not have a valid signature.
- `TypeError` – This exception is raised if *token* is not *bytes*.

class `cryptology.fernet.MultiFernet` (*fernets*)

New in version 0.7.

This class implements key rotation for Fernet. It takes a list of `Fernet` instances, and implements the same API:

```
>>> from cryptology.fernet import Fernet, MultiFernet
>>> key1 = Fernet(Fernet.generate_key())
>>> key2 = Fernet(Fernet.generate_key())
>>> f = MultiFernet([key1, key2])
>>> token = f.encrypt(b"Secret message!")
>>> token
'...'
>>> f.decrypt(token)
'Secret message!'
```

`MultiFernet` performs all encryption options using the *first* key in the list provided. `MultiFernet` attempts to decrypt tokens with each key in turn. A `cryptology.fernet.InvalidToken` exception is raised if the correct key is not found in the list provided.

Key rotation makes it easy to replace old keys. You can add your new key at the front of the list to start encrypting new messages, and remove old keys as they are no longer needed.

`class cryptography.fernet.InvalidToken`
 See `Fernet.decrypt()` for more information.

Using passwords with Fernet

It is possible to use passwords with Fernet. To do this, you need to run the password through a key derivation function such as `PBKDF2HMAC`, `bcrypt` or `Scrypt`.

```
>>> import base64
>>> import os
>>> from cryptography.fernet import Fernet
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.kdf.pbkdf2 import PBKDF2HMAC
>>> password = b"password"
>>> salt = os.urandom(16)
>>> kdf = PBKDF2HMAC(
...     algorithm=hashes.SHA256(),
...     length=32,
...     salt=salt,
...     iterations=100000,
...     backend=default_backend()
... )
>>> key = base64.urlsafe_b64encode(kdf.derive(password))
>>> f = Fernet(key)
>>> token = f.encrypt(b"Secret message!")
>>> token
'...'
>>> f.decrypt(token)
'Secret message!'
```

In this scheme, the salt has to be stored in a retrievable location in order to derive the same key from the password in the future.

The iteration count used should be adjusted to be as high as your server can tolerate. A good default is at least 100,000 iterations which is what Django recommended in 2014.

Implementation

Fernet is built on top of a number of standard cryptographic primitives. Specifically it uses:

- `AES` in `CBC` mode with a 128-bit key for encryption; using `PKCS7` padding.
- `HMAC` using `SHA256` for authentication.
- Initialization vectors are generated using `os.urandom()`.

For complete details consult the [specification](#).

Limitations

Fernet is ideal for encrypting data that easily fits in memory. As a design feature it does not expose unauthenticated bytes. Unfortunately, this makes it generally unsuitable for very large files at this time.

X.509

X.509 is an ITU-T standard for a [public key infrastructure](#). X.509v3 is defined in [RFC 5280](#) (which obsoletes [RFC 2459](#) and [RFC 3280](#)). X.509 certificates are commonly used in protocols like [TLS](#).

Tutorial

X.509 certificates are used to authenticate clients and servers. The most common use case is for web servers using [HTTPS](#).

Creating a Certificate Signing Request (CSR)

When obtaining a certificate from a certificate authority (CA), the usual flow is:

1. You generate a private/public key pair.
2. You create a request for a certificate, which is signed by your key (to prove that you own that key).
3. You give your CSR to a CA (but *not* the private key).
4. The CA validates that you own the resource (e.g. domain) you want a certificate for.
5. The CA gives you a certificate, signed by them, which identifies your public key, and the resource you are authenticated for.
6. You configure your server to use that certificate, combined with your private key, to server traffic.

If you want to obtain a certificate from a typical commercial CA, here's how. First, you'll need to generate a private key, we'll generate an RSA key (these are the most common types of keys on the web right now):

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import serialization
>>> from cryptography.hazmat.primitives.asymmetric import rsa
>>> # Generate our key
>>> key = rsa.generate_private_key(
...     public_exponent=65537,
...     key_size=2048,
...     backend=default_backend()
... )
>>> # Write our key to disk for safe keeping
>>> with open("path/to/store/key.pem", "wb") as f:
...     f.write(key.private_bytes(
...         encoding=serialization.Encoding.PEM,
...         format=serialization.PrivateFormat.TraditionalOpenSSL,
...         encryption_algorithm=serialization.BestAvailableEncryption(b"passphrase"),
...     ))
```

If you've already generated a key you can load it with `load_pem_private_key()`.

Next we need to generate a certificate signing request. A typical CSR contains a few details:

- Information about our public key (including a signature of the entire body).
- Information about who *we* are.
- Information about what domains this certificate is for.

```

>>> from cryptography import x509
>>> from cryptography.x509.oid import NameOID
>>> from cryptography.hazmat.primitives import hashes
>>> # Generate a CSR
>>> csr = x509.CertificateSigningRequestBuilder().subject_name(x509.Name([
...     # Provide various details about who we are.
...     x509.NameAttribute(NameOID.COUNTRY_NAME, u"US"),
...     x509.NameAttribute(NameOID.STATE_OR_PROVINCE_NAME, u"CA"),
...     x509.NameAttribute(NameOID.LOCALITY_NAME, u"San Francisco"),
...     x509.NameAttribute(NameOID.ORGANIZATION_NAME, u"My Company"),
...     x509.NameAttribute(NameOID.COMMON_NAME, u"mysite.com"),
... ])).add_extension(
...     x509.SubjectAlternativeName([
...         # Describe what sites we want this certificate for.
...         x509.DNSName(u"mysite.com"),
...         x509.DNSName(u"www.mysite.com"),
...         x509.DNSName(u"subdomain.mysite.com"),
...     ]),
...     critical=False,
...     # Sign the CSR with our private key.
... ).sign(key, hashes.SHA256(), default_backend())
>>> # Write our CSR out to disk.
>>> with open("path/to/csr.pem", "wb") as f:
...     f.write(csr.public_bytes(serialization.Encoding.PEM))

```

Now we can give our CSR to a CA, who will give a certificate to us in return.

Creating a self-signed certificate

While most of the time you want a certificate that has been *signed* by someone else (i.e. a certificate authority), so that trust is established, sometimes you want to create a self-signed certificate. Self-signed certificates are not issued by a certificate authority, but instead they are signed by the private key corresponding to the public key they embed.

This means that other people don't trust these certificates, but it also means they can be issued very easily. In general the only use case for a self-signed certificate is local testing, where you don't need anyone else to trust your certificate.

Like generating a CSR, we start with creating a new private key:

```

>>> # Generate our key
>>> key = rsa.generate_private_key(
...     public_exponent=65537,
...     key_size=2048,
...     backend=default_backend()
... )
>>> # Write our key to disk for safe keeping
>>> with open("path/to/store/key.pem", "wb") as f:
...     f.write(key.private_bytes(
...         encoding=serialization.Encoding.PEM,
...         format=serialization.PrivateFormat.TraditionalOpenSSL,
...         encryption_algorithm=serialization.BestAvailableEncryption(b"passphrase"),
...     ))

```

Then we generate the certificate itself:

```

>>> # Various details about who we are. For a self-signed certificate the
>>> # subject and issuer are always the same.
>>> subject = issuer = x509.Name([

```

```
...     x509.NameAttribute(NameOID.COUNTRY_NAME, u"US"),
...     x509.NameAttribute(NameOID.STATE_OR_PROVINCE_NAME, u"CA"),
...     x509.NameAttribute(NameOID.LOCALITY_NAME, u"San Francisco"),
...     x509.NameAttribute(NameOID.ORGANIZATION_NAME, u"My Company"),
...     x509.NameAttribute(NameOID.COMMON_NAME, u"mysite.com"),
... ]
>>> cert = x509.CertificateBuilder().subject_name(
...     subject
... ).issuer_name(
...     issuer
... ).public_key(
...     key.public_key()
... ).serial_number(
...     x509.random_serial_number()
... ).not_valid_before(
...     datetime.datetime.utcnow()
... ).not_valid_after(
...     # Our certificate will be valid for 10 days
...     datetime.datetime.utcnow() + datetime.timedelta(days=10)
... ).add_extension(
...     x509.SubjectAlternativeName([x509.DNSName(u"localhost")]),
...     critical=False,
...     # Sign our certificate with our private key
... ).sign(key, hashes.SHA256(), default_backend())
>>> # Write our certificate out to disk.
>>> with open("path/to/certificate.pem", "wb") as f:
...     f.write(cert.public_bytes(serialization.Encoding.PEM))
```

And now we have a private key and certificate that can be used for local testing.

Determining Certificate or Certificate Signing Request Key Type

Certificates and certificate signing requests can be issued with multiple key types. You can determine what the key type is by using `isinstance` checks:

```
>>> public_key = cert.public_key()
>>> if isinstance(public_key, rsa.RSAPublicKey):
...     # Do something RSA specific
... elif isinstance(public_key, ec.EllipticCurvePublicKey):
...     # Do something EC specific
... else:
...     # Remember to handle this case
```

Certificate Transparency

Certificate Transparency is a set of protocols specified in [RFC 6962](#) which allow X.509 certificates to be sent to append-only logs and have small cryptographic proofs that a certificate has been publicly logged. This allows for external auditing of the certificates that a certificate authority has issued.

class `cryptography.x509.certificate_transparency.SignedCertificateTimestamp`
New in version 2.0.

SignedCertificateTimestamps (SCTs) are small cryptographically signed assertions that the specified certificate has been submitted to a Certificate Transparency Log, and that it will be part of the public log within some time period, this is called the “maximum merge delay” (MMD) and each log specifies its own.

version**Type** *Version*

The SCT version as an enumeration. Currently only one version has been specified.

log_id**Type** bytes

An opaque identifier, indicating which log this SCT is from. This is the SHA256 hash of the log's public key.

timestamp**Type** `datetime.datetime`

A naïve datetime representing the time in UTC at which the log asserts the certificate had been submitted to it.

entry_type**Type** *LogEntryType*

The type of submission to the log that this SCT is for. Log submissions can either be certificates themselves or “pre-certificates” which indicate a binding-intent to issue a certificate for the same data, with SCTs embedded in it.

class `cryptography.x509.certificate_transparency.Version`
New in version 2.0.

An enumeration for SignedCertificateTimestamp versions.

v1

For version 1 SignedCertificateTimestamps.

class `cryptography.x509.certificate_transparency.LogEntryType`
New in version 2.0.

An enumeration for SignedCertificateTimestamp log entry types.

X509_CERTIFICATE

For SCTs corresponding to X.509 certificates.

PRE_CERTIFICATE

For SCTs corresponding to pre-certificates.

X.509 Reference

Loading Certificates

`cryptography.x509.load_pem_x509_certificate` (*data*, *backend*)
New in version 0.7.

Deserialize a certificate from PEM encoded data. PEM certificates are base64 decoded and have delimiters that look like -----BEGIN CERTIFICATE-----.

Parameters

- **data** (*bytes*) – The PEM encoded certificate data.
- **backend** – A backend supporting the *X509Backend* interface.

Returns An instance of *Certificate*.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> cert = x509.load_pem_x509_certificate(pem_data, default_backend())
>>> cert.serial_number
2
```

`cryptography.x509.load_der_x509_certificate(data, backend)`

New in version 0.7.

Deserialize a certificate from DER encoded data. DER is a binary format and is commonly found in files with the `.cer` extension (although file extensions are not a guarantee of encoding type).

Parameters

- **data** (*bytes*) – The DER encoded certificate data.
- **backend** – A backend supporting the *X509Backend* interface.

Returns An instance of *Certificate*.

Loading Certificate Revocation Lists

`cryptography.x509.load_pem_x509_crl(data, backend)`

New in version 1.1.

Deserialize a certificate revocation list (CRL) from PEM encoded data. PEM requests are base64 decoded and have delimiters that look like `-----BEGIN X509 CRL-----`.

Parameters

- **data** (*bytes*) – The PEM encoded request data.
- **backend** – A backend supporting the *X509Backend* interface.

Returns An instance of *CertificateRevocationList*.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> crl = x509.load_pem_x509_crl(pem_crl_data, default_backend())
>>> isinstance(crl.signature_hash_algorithm, hashes.SHA256)
True
```

`cryptography.x509.load_der_x509_crl(data, backend)`

New in version 1.1.

Deserialize a certificate revocation list (CRL) from DER encoded data. DER is a binary format.

Parameters

- **data** (*bytes*) – The DER encoded request data.
- **backend** – A backend supporting the *X509Backend* interface.

Returns An instance of *CertificateRevocationList*.

Loading Certificate Signing Requests

`cryptography.x509.load_pem_x509_csr(data, backend)`

New in version 0.9.

Deserialize a certificate signing request (CSR) from PEM encoded data. PEM requests are base64 decoded and have delimiters that look like -----BEGIN CERTIFICATE REQUEST-----. This format is also known as PKCS#10.

Parameters

- **data** (*bytes*) – The PEM encoded request data.
- **backend** – A backend supporting the *X509Backend* interface.

Returns An instance of *CertificateSigningRequest*.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> csr = x509.load_pem_x509_csr(pem_req_data, default_backend())
>>> isinstance(csr.signature_hash_algorithm, hashes.SHA1)
True
```

`cryptography.x509.load_der_x509_csr(data, backend)`

New in version 0.9.

Deserialize a certificate signing request (CSR) from DER encoded data. DER is a binary format and is not commonly used with CSRs.

Parameters

- **data** (*bytes*) – The DER encoded request data.
- **backend** – A backend supporting the *X509Backend* interface.

Returns An instance of *CertificateSigningRequest*.

X.509 Certificate Object

`class cryptography.x509.Certificate`

New in version 0.7.

version

Type *Version*

The certificate version as an enumeration. Version 3 certificates are the latest version and also the only type you should see in practice.

Raises `cryptography.x509.InvalidVersion` – If the version in the certificate is not a known *X.509 version*.

```
>>> cert.version
<Version.v3: 2>
```

`fingerprint(algorithm)`

Parameters `algorithm` – The *HashAlgorithm* that will be used to generate the fingerprint.

Return bytes The fingerprint using the supplied hash algorithm, as bytes.

```
>>> from cryptography.hazmat.primitives import hashes
>>> cert.fingerprint(hashes.SHA256())
'\x86\xd2\x187Gc\xfc\xe7} [+E9\x8d\xb4\x8f\x10\xe5S\xda\x18u\xbe]
↪a\x03\x08[\xac\xa04?'
```

serial_number**Type** int

The serial as a Python integer.

```
>>> cert.serial_number
2
```

public_key()

The public key associated with the certificate.

Returns *RSAPublicKey* or *DSAPublicKey* or *EllipticCurvePublicKey*

```
>>> from cryptography.hazmat.primitives.asymmetric import rsa
>>> public_key = cert.public_key()
>>> isinstance(public_key, rsa.RSAPublicKey)
True
```

not_valid_before**Type** datetime.datetime

A naïve datetime representing the beginning of the validity period for the certificate in UTC. This value is inclusive.

```
>>> cert.not_valid_before
datetime.datetime(2010, 1, 1, 8, 30)
```

not_valid_after**Type** datetime.datetime

A naïve datetime representing the end of the validity period for the certificate in UTC. This value is inclusive.

```
>>> cert.not_valid_after
datetime.datetime(2030, 12, 31, 8, 30)
```

issuer

New in version 0.8.

Type *Name*The *Name* of the issuer.**subject**

New in version 0.8.

Type *Name*The *Name* of the subject.**signature_hash_algorithm****Type** *HashAlgorithm*Returns the *HashAlgorithm* which was used in signing this certificate.

```
>>> from cryptography.hazmat.primitives import hashes
>>> isinstance(cert.signature_hash_algorithm, hashes.SHA256)
True
```

signature_algorithm_oid

New in version 1.6.

Type *ObjectIdentifier*

Returns the *ObjectIdentifier* of the signature algorithm used to sign the certificate. This will be one of the OIDs from *SignatureAlgorithmOID*.

```
>>> cert.signature_algorithm_oid
<ObjectIdentifier(oid=1.2.840.113549.1.1.11, name=sha256WithRSAEncryption)>
```

extensions

Type *Extensions*

The extensions encoded in the certificate.

Raises

- ***cryptography.x509.DuplicateExtension*** – If more than one extension of the same type is found within the certificate.
- ***cryptography.x509.UnsupportedGeneralNameType*** – If an extension contains a general name that is not supported.
- ***UnicodeError*** – If an extension contains IDNA encoding that is invalid or not compliant with IDNA 2008.

```
>>> for ext in cert.extensions:
...     print(ext)
<Extension(oid=<ObjectIdentifier(oid=2.5.29.35, name=authorityKeyIdentifier)>,
↳ critical=False, value=<AuthorityKeyIdentifier(key_identifier='\xe4}_
↳ \xd1\\\x95\x86\x08, \x05\xae\xbeu\xb6e\xa7\xd9]\xa8f', authority_cert_
↳ issuer=None, authority_cert_serial_number=None)>>
<Extension(oid=<ObjectIdentifier(oid=2.5.29.14, name=subjectKeyIdentifier)>,
↳ critical=False, value=<SubjectKeyIdentifier(digest='X\x01\x84
↳ $\x1b\xbc+R\x94J=\xa5\x10r\x14Q\x15\xaf:\xc9')>>
<Extension(oid=<ObjectIdentifier(oid=2.5.29.15, name=keyUsage)>,
↳ critical=True, value=<KeyUsage(digital_signature=False, content_
↳ commitment=False, key_encipherment=False, data_encipherment=False, key_
↳ agreement=False, key_cert_sign=True, crl_sign=True, encipher_only=None,
↳ decipher_only=None)>>
<Extension(oid=<ObjectIdentifier(oid=2.5.29.32, name=certificatePolicies)>,
↳ critical=False, value=<CertificatePolicies([<PolicyInformation(policy_
↳ identifier=<ObjectIdentifier(oid=2.16.840.1.101.3.2.1.48.1, name=Unknown
↳ OID)>, policy_qualifiers=None)>])>>
<Extension(oid=<ObjectIdentifier(oid=2.5.29.19, name=basicConstraints)>,
↳ critical=True, value=<BasicConstraints(ca=True, path_length=None)>>
```

signature

New in version 1.2.

Type bytes

The bytes of the certificate's signature.

tbs_certificate_bytes

New in version 1.2.

Type bytes

The DER encoded bytes payload (as defined by [RFC 5280](#)) that is hashed and then signed by the private key of the certificate's issuer. This data may be used to validate a signature, but use extreme caution as certificate validation is a complex problem that involves much more than just signature checks.

public_bytes (*encoding*)

New in version 1.0.

Parameters *encoding* – The *Encoding* that will be used to serialize the certificate.

Return bytes The data that can be written to a file or sent over the network to be verified by clients.

X.509 CRL (Certificate Revocation List) Object

class cryptography.x509.CertificateRevocationList

New in version 1.0.

A CertificateRevocationList is an object representing a list of revoked certificates. The object is iterable and will yield the RevokedCertificate objects stored in this CRL.

```
>>> len(crl)
1
>>> revoked_certificate = crl[0]
>>> type(revoked_certificate)
<class 'cryptography.hazmat.backends.openssl.x509._RevokedCertificate'>
>>> for r in crl:
...     print(r.serial_number)
0
```

fingerprint (*algorithm*)

Parameters *algorithm* – The *HashAlgorithm* that will be used to generate the fingerprint.

Return bytes The fingerprint using the supplied hash algorithm, as bytes.

```
>>> from cryptography.hazmat.primitives import hashes
>>> crl.fingerprint(hashes.SHA256())
'e\xcf.\xc4:\x83?1\xdc\xfc\x95\xd7\xb3\x87\xb3\x8e\xf8\xb93!
↪\x87\x07\x9d\x1b\xb4!\xb9\xe4W\xf4\x1f'
```

signature_hash_algorithm

Type *HashAlgorithm*

Returns the *HashAlgorithm* which was used in signing this CRL.

```
>>> from cryptography.hazmat.primitives import hashes
>>> isinstance(crl.signature_hash_algorithm, hashes.SHA256)
True
```

signature_algorithm_oid

New in version 1.6.

Type *ObjectIdentifier*

Returns the *ObjectIdentifier* of the signature algorithm used to sign the CRL. This will be one of the OIDs from *SignatureAlgorithmOID*.

```
>>> crl.signature_algorithm_oid
<ObjectIdentifier(oid=1.2.840.113549.1.1.11, name=sha256WithRSAEncryption)>
```

issuer**Type** *Name*The *Name* of the issuer.

```
>>> crl.issuer
<Name ([<NameAttribute (oid=<ObjectIdentifier (oid=2.5.4.6, name=countryName)>, ↵
↵value=u'US')>, <NameAttribute (oid=<ObjectIdentifier (oid=2.5.4.3, ↵
↵name=commonName)>, value=u'cryptography.io')>])>
```

next_update**Type** `datetime.datetime`

A naïve datetime representing when the next update to this CRL is expected.

```
>>> crl.next_update
datetime.datetime(2016, 1, 1, 0, 0)
```

last_update**Type** `datetime.datetime`

A naïve datetime representing when the this CRL was last updated.

```
>>> crl.last_update
datetime.datetime(2015, 1, 1, 0, 0)
```

extensions**Type** *Extensions*

The extensions encoded in the CRL.

signature

New in version 1.2.

Type `bytes`

The bytes of the CRL's signature.

tbs_certlist_bytes

New in version 1.2.

Type `bytes`

The DER encoded bytes payload (as defined by [RFC 5280](#)) that is hashed and then signed by the private key of the CRL's issuer. This data may be used to validate a signature, but use extreme caution as CRL validation is a complex problem that involves much more than just signature checks.

public_bytes (*encoding*)

New in version 1.2.

Parameters `encoding` – The *Encoding* that will be used to serialize the certificate revocation list.

Return bytes The data that can be written to a file or sent over the network and used as part of a certificate verification process.

X.509 Certificate Builder

`class cryptography.x509.CertificateBuilder`

New in version 1.0.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.asymmetric import rsa
>>> from cryptography.x509.oid import NameOID
>>> import datetime
>>> one_day = datetime.timedelta(1, 0, 0)
>>> private_key = rsa.generate_private_key(
...     public_exponent=65537,
...     key_size=2048,
...     backend=default_backend()
... )
>>> public_key = private_key.public_key()
>>> builder = x509.CertificateBuilder()
>>> builder = builder.subject_name(x509.Name([
...     x509.NameAttribute(NameOID.COMMON_NAME, u'cryptography.io'),
... ]))
>>> builder = builder.issuer_name(x509.Name([
...     x509.NameAttribute(NameOID.COMMON_NAME, u'cryptography.io'),
... ]))
>>> builder = builder.not_valid_before(datetime.datetime.today() - one_day)
>>> builder = builder.not_valid_after(datetime.datetime(2018, 8, 2))
>>> builder = builder.serial_number(x509.random_serial_number())
>>> builder = builder.public_key(public_key)
>>> builder = builder.add_extension(
...     x509.SubjectAlternativeName(
...         [x509.DNSName(u'cryptography.io')]
...     ),
...     critical=False
... )
>>> builder = builder.add_extension(
...     x509.BasicConstraints(ca=False, path_length=None), critical=True,
... )
>>> certificate = builder.sign(
...     private_key=private_key, algorithm=hashes.SHA256(),
...     backend=default_backend()
... )
>>> isinstance(certificate, x509.Certificate)
True
```

issuer_name (*name*)

Sets the issuer's distinguished name.

Parameters **name** – The *Name* that describes the issuer (CA).

subject_name (*name*)

Sets the subject's distinguished name.

Parameters **name** – The *Name* that describes the subject.

public_key (*public_key*)

Sets the subject's public key.

Parameters **public_key** – The subject's public key. This can be one of *RSAPublicKey*, *DSAPublicKey* or *EllipticCurvePublicKey*

serial_number (*serial_number*)

Sets the certificate's serial number (an integer). The CA's policy determines how it attributes serial numbers to certificates. This number must uniquely identify the certificate given the issuer. [CABForum Guidelines](#) require entropy in the serial number to provide protection against hash collision attacks. For more information on secure random number generation, see [Random number generation](#).

Parameters **serial_number** – Integer number that will be used by the CA to identify this certificate (most notably during certificate revocation checking). Users should consider using `random_serial_number()` when possible.

not_valid_before (*time*)

Sets the certificate's activation time. This is the time from which clients can start trusting the certificate. It may be different from the time at which the certificate was created.

Parameters **time** – The `datetime.datetime` object (in UTC) that marks the activation time for the certificate. The certificate may not be trusted clients if it is used before this time.

not_valid_after (*time*)

Sets the certificate's expiration time. This is the time from which clients should no longer trust the certificate. The CA's policy will determine how long the certificate should remain in use.

Parameters **time** – The `datetime.datetime` object (in UTC) that marks the expiration time for the certificate. The certificate may not be trusted clients if it is used after this time.

add_extension (*extension, critical*)

Adds an X.509 extension to the certificate.

Parameters

- **extension** – An extension conforming to the `ExtensionType` interface.
- **critical** – Set to `True` if the extension must be understood and handled by whoever reads the certificate.

sign (*private_key, algorithm, backend*)

Sign the certificate using the CA's private key.

Parameters

- **private_key** – The `RSAPrivateKey`, `DSAPrivateKey` or `EllipticCurvePrivateKey` that will be used to sign the certificate.
- **algorithm** – The `HashAlgorithm` that will be used to generate the signature.
- **backend** – Backend that will be used to build the certificate. Must support the `X509Backend` interface.

Returns `Certificate`

X.509 CSR (Certificate Signing Request) Object

class `cryptography.x509.CertificateSigningRequest`

New in version 0.9.

public_key ()

The public key associated with the request.

Returns `RSAPublicKey` or `DSAPublicKey` or `EllipticCurvePublicKey`

```
>>> from cryptography.hazmat.primitives.asymmetric import rsa
>>> public_key = csr.public_key()
```

```
>>> isinstance(public_key, rsa.RSAPublicKey)
True
```

subject

Type *Name*

The *Name* of the subject.

signature_hash_algorithm

Type *HashAlgorithm*

Returns the *HashAlgorithm* which was used in signing this request.

```
>>> from cryptography.hazmat.primitives import hashes
>>> isinstance(csr.signature_hash_algorithm, hashes.SHA1)
True
```

signature_algorithm_oid

New in version 1.6.

Type *ObjectIdentifier*

Returns the *ObjectIdentifier* of the signature algorithm used to sign the request. This will be one of the OIDs from *SignatureAlgorithmOID*.

```
>>> csr.signature_algorithm_oid
<ObjectIdentifier(oid=1.2.840.113549.1.1.5, name=sha1WithRSAEncryption)>
```

extensions

Type *Extensions*

The extensions encoded in the certificate signing request.

Raises

- ***cryptography.x509.DuplicateExtension*** – If more than one extension of the same type is found within the certificate signing request.
- ***cryptography.x509.UnsupportedGeneralNameType*** – If an extension contains a general name that is not supported.
- ***UnicodeError*** – If an extension contains IDNA encoding that is invalid or not compliant with IDNA 2008.

public_bytes (*encoding*)

New in version 1.0.

Parameters **encoding** – The *Encoding* that will be used to serialize the certificate request.

Return bytes The data that can be written to a file or sent over the network to be signed by the certificate authority.

signature

New in version 1.2.

Type bytes

The bytes of the certificate signing request's signature.

tbs_certrequest_bytes

New in version 1.2.

Type bytes

The DER encoded bytes payload (as defined by [RFC 2986](#)) that is hashed and then signed by the private key (corresponding to the public key embedded in the CSR). This data may be used to validate the CSR signature.

is_signature_valid

New in version 1.3.

Returns True if the CSR signature is correct, False otherwise.

X.509 Certificate Revocation List Builder

class cryptography.x509.CertificateRevocationListBuilder

New in version 1.2.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.asymmetric import rsa
>>> from cryptography.x509.oid import NameOID
>>> import datetime
>>> one_day = datetime.timedelta(1, 0, 0)
>>> private_key = rsa.generate_private_key(
...     public_exponent=65537,
...     key_size=2048,
...     backend=default_backend()
... )
>>> builder = x509.CertificateRevocationListBuilder()
>>> builder = builder.issuer_name(x509.Name([
...     x509.NameAttribute(NameOID.COMMON_NAME, u'cryptography.io CA'),
... ]))
>>> builder = builder.last_update(datetime.datetime.today())
>>> builder = builder.next_update(datetime.datetime.today() + one_day)
>>> revoked_cert = x509.RevokedCertificateBuilder().serial_number(
...     333
... ).revocation_date(
...     datetime.datetime.today()
... ).build(default_backend())
>>> builder = builder.add_revoked_certificate(revoked_cert)
>>> crl = builder.sign(
...     private_key=private_key, algorithm=hashes.SHA256(),
...     backend=default_backend()
... )
>>> len(crl)
1
```

issuer_name (*name*)

Sets the issuer's distinguished name.

Parameters *name* – The *Name* that describes the issuer (CA).

last_update (*time*)

Sets this CRL's activation time. This is the time from which clients can start trusting this CRL. It may be different from the time at which this CRL was created. This is also known as the `thisUpdate` time.

Parameters *time* – The `datetime.datetime` object (in UTC) that marks the activation time for this CRL. The CRL may not be trusted if it is used before this time.

next_update (*time*)

Sets this CRL's next update time. This is the time by which a new CRL will be issued. The CA is allowed to issue a new CRL before this date, however clients are not required to check for it.

Parameters **time** – The `datetime.datetime` object (in UTC) that marks the next update time for this CRL.

add_extension (*extension, critical*)

Adds an X.509 extension to this CRL.

Parameters

- **extension** – An extension with the `ExtensionType` interface.
- **critical** – Set to `True` if the extension must be understood and handled by whoever reads the CRL.

add_revoked_certificate (*revoked_certificate*)

Adds a revoked certificate to this CRL.

Parameters **revoked_certificate** – An instance of `RevokedCertificate`. These can be obtained from an existing CRL or created with `RevokedCertificateBuilder`.

sign (*private_key, algorithm, backend*)

Sign this CRL using the CA's private key.

Parameters

- **private_key** – The `RSAPrivateKey`, `DSAPrivateKey` or `EllipticCurvePrivateKey` that will be used to sign the certificate.
- **algorithm** – The `HashAlgorithm` that will be used to generate the signature.
- **backend** – Backend that will be used to build the CRL. Must support the `X509Backend` interface.

Returns `CertificateRevocationList`

X.509 Revoked Certificate Object

class `cryptography.x509.RevokedCertificate`

New in version 1.0.

serial_number

Type `int`

An integer representing the serial number of the revoked certificate.

```
>>> revoked_certificate.serial_number
0
```

revocation_date

Type `datetime.datetime`

A naïve datetime representing the date this certificates was revoked.

```
>>> revoked_certificate.revocation_date
datetime.datetime(2015, 1, 1, 0, 0)
```

extensions

Type *Extensions*

The extensions encoded in the revoked certificate.

```
>>> for ext in revoked_certificate.extensions:
...     print(ext)
<Extension(oid=<ObjectIdentifier(oid=2.5.29.24, name=invalidityDate)>,
critical=False, value=<InvalidityDate(invalidity_date=2015-01-01 00:00:00)>)>
<Extension(oid=<ObjectIdentifier(oid=2.5.29.21, name=cRLReason)>,
critical=False, value=<CRLReason(reason=ReasonFlags.key_compromise)>)>
```

X.509 Revoked Certificate Builder**class** cryptography.x509.**RevokedCertificateBuilder**

This class is used to create *RevokedCertificate* objects that can be used with the *CertificateRevocationListBuilder*.

New in version 1.2.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> import datetime
>>> builder = x509.RevokedCertificateBuilder()
>>> builder = builder.revocation_date(datetime.datetime.today())
>>> builder = builder.serial_number(3333)
>>> revoked_certificate = builder.build(default_backend())
>>> isinstance(revoked_certificate, x509.RevokedCertificate)
True
```

serial_number (*serial_number*)

Sets the revoked certificate's serial number.

Parameters **serial_number** – Integer number that is used to identify the revoked certificate.

revocation_date (*time*)

Sets the certificate's revocation date.

Parameters **time** – The `datetime.datetime` object (in UTC) that marks the revocation time for the certificate.

add_extension (*extension, critical*)

Adds an X.509 extension to this revoked certificate.

Parameters

- **extension** – An instance of one of the *CRL entry extensions*.
- **critical** – Set to `True` if the extension must be understood and handled.

build (*backend*)

Create a revoked certificate object using the provided backend.

Parameters **backend** – Backend that will be used to build the revoked certificate. Must support the *X509Backend* interface.

Returns *RevokedCertificate*

X.509 CSR (Certificate Signing Request) Builder Object

class cryptography.x509.CertificateSigningRequestBuilder
New in version 1.0.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.asymmetric import rsa
>>> from cryptography.x509.oid import NameOID
>>> private_key = rsa.generate_private_key(
...     public_exponent=65537,
...     key_size=2048,
...     backend=default_backend()
... )
>>> builder = x509.CertificateSigningRequestBuilder()
>>> builder = builder.subject_name(x509.Name([
...     x509.NameAttribute(NameOID.COMMON_NAME, u'cryptography.io'),
... ]))
>>> builder = builder.add_extension(
...     x509.BasicConstraints(ca=False, path_length=None), critical=True,
... )
>>> request = builder.sign(
...     private_key, hashes.SHA256(), default_backend()
... )
>>> isinstance(request, x509.CertificateSigningRequest)
True
```

subject_name (*name*)

Parameters *name* – The *Name* of the certificate subject.

Returns A new *CertificateSigningRequestBuilder*.

add_extension (*extension, critical*)

Parameters

- **extension** – An extension conforming to the *ExtensionType* interface.
- **critical** – Set to *True* if the extension must be understood and handled by whoever reads the certificate.

Returns A new *CertificateSigningRequestBuilder*.

sign (*private_key, algorithm, backend*)

Parameters

- **backend** – Backend that will be used to sign the request. Must support the *X509Backend* interface.
- **private_key** – The *RSAPrivateKey*, *DSAPrivateKey* or *EllipticCurvePrivateKey* that will be used to sign the request. When the request is signed by a certificate authority, the private key's associated public key will be stored in the resulting certificate.
- **algorithm** – The *HashAlgorithm* that will be used to generate the request signature.

Returns A new *CertificateSigningRequest*.

class cryptography.x509.Name
New in version 0.8.

An X509 Name is an ordered list of attributes. The object is iterable to get every attribute or you can use `Name.get_attributes_for_oid()` to obtain the specific type you want. Names are sometimes represented as a slash or comma delimited string (e.g. `/CN=mydomain.com/O=My Org/C=US` or `CN=mydomain.com, O=My Org, C=US`).

Technically, a Name is a list of *sets* of attributes, called *Relative Distinguished Names* or *RDNs*, although multi-valued RDNs are rarely encountered. The iteration order of values within a multi-valued RDN is undefined. If you need to handle multi-valued RDNs, the `rdns` property gives access to an ordered list of *RelativeDistinguishedName* objects.

A Name can be initialized with an iterable of *NameAttribute* (the common case where each RDN has a single attribute) or an iterable of *RelativeDistinguishedName* objects (in the rare case of multi-valued RDNs).

```
>>> len(cert.subject)
3
>>> for attribute in cert.subject:
...     print(attribute)
<NameAttribute(oid=<ObjectIdentifier(oid=2.5.4.6, name=countryName)>, value=u'US
↳')>
<NameAttribute(oid=<ObjectIdentifier(oid=2.5.4.10, name=organizationName)>,
↳value=u'Test Certificates 2011')>
<NameAttribute(oid=<ObjectIdentifier(oid=2.5.4.3, name=commonName)>, value=u'Good
↳CA')>
```

rdns

New in version 1.6.

Type list of *RelativeDistinguishedName*

get_attributes_for_oid(oid)

Parameters `oid` – An *ObjectIdentifier* instance.

Returns A list of *NameAttribute* instances that match the OID provided. If nothing matches an empty list will be returned.

```
>>> cert.subject.get_attributes_for_oid(NameOID.COMMON_NAME)
[<NameAttribute(oid=<ObjectIdentifier(oid=2.5.4.3, name=commonName)>, value=u
↳'Good CA')>]
```

public_bytes(backend)

New in version 1.6.

Parameters `backend` – A backend supporting the *X509Backend* interface.

Return bytes The DER encoded name.

class cryptography.x509.Version

New in version 0.7.

An enumeration for X.509 versions.

v1

For version 1 X.509 certificates.

v3

For version 3 X.509 certificates.

class cryptography.x509.NameAttribute

New in version 0.8.

An X.509 name consists of a list of *RelativeDistinguishedName* instances, which consist of a set of *NameAttribute* instances.

oid

Type *ObjectIdentifier*

The attribute OID.

value

Type *text*

The value of the attribute.

class `cryptography.x509.RelativeDistinguishedName` (*attributes*)

New in version 1.6.

A relative distinguished name is a non-empty set of name attributes. The object is iterable to get every attribute.

get_attributes_for_oid (*oid*)

Parameters *oid* – An *ObjectIdentifier* instance.

Returns A list of *NameAttribute* instances that match the OID provided. The list should contain zero or one values.

class `cryptography.x509.ObjectIdentifier`

New in version 0.8.

Object identifiers (frequently seen abbreviated as OID) identify the type of a value (see: *NameAttribute*).

dotted_string

Type *str*

The dotted string value of the OID (e.g. "2.5.4.3")

General Name Classes

class `cryptography.x509.GeneralName`

New in version 0.9.

This is the generic interface that all the following classes are registered against.

class `cryptography.x509.RFC822Name` (*value*)

New in version 0.9.

This corresponds to an email address. For example, `user@example.com`.

value

Type *text*

class `cryptography.x509.DNSName` (*value*)

New in version 0.9.

This corresponds to a domain name. For example, `cryptography.io`.

value

Type *text*

class `cryptography.x509.DirectoryName` (*value*)
New in version 0.9.

This corresponds to a directory name.

value

Type *Name*

class `cryptography.x509.UniformResourceIdentifier` (*value*)
New in version 0.9.

This corresponds to a uniform resource identifier. For example, `https://cryptography.io`. The URI is parsed and IDNA decoded (see [RFC 5895](#)).

Note: URIs that do not contain `://` in them will not be decoded.

value

Type *text*

class `cryptography.x509.IPAddress` (*value*)
New in version 0.9.

This corresponds to an IP address.

value

Type *IPv4Address, IPv6Address, IPv4Network, or IPv6Network.*

class `cryptography.x509.RegisteredID` (*value*)
New in version 0.9.

This corresponds to a registered ID.

value

Type *ObjectIdentifier*

class `cryptography.x509.OtherName` (*type_id, value*)
New in version 1.0.

This corresponds to an otherName. An otherName has a type identifier and a value represented in binary DER format.

type_id

Type *ObjectIdentifier*

value

Type *bytes*

X.509 Extensions

class `cryptography.x509.Extensions`
New in version 0.9.

An X.509 Extensions instance is an ordered list of extensions. The object is iterable to get every extension.

get_extension_for_oid (*oid*)

Parameters *oid* – An *ObjectIdentifier* instance.

Returns An instance of the extension class.

Raises `cryptography.x509.ExtensionNotFound` – If the certificate does not have the extension requested.

```
>>> from cryptography.x509.oid import ExtensionOID
>>> cert.extensions.get_extension_for_oid(ExtensionOID.BASIC_CONSTRAINTS)
<Extension(oid=<ObjectIdentifier(oid=2.5.29.19, name=basicConstraints)>,
critical=True, value=<BasicConstraints(ca=True, path_length=None)>)>
```

get_extension_for_class (*extclass*)

New in version 1.1.

Parameters `extclass` – An extension class.

Returns An instance of the extension class.

Raises `cryptography.x509.ExtensionNotFound` – If the certificate does not have the extension requested.

```
>>> from cryptography import x509
>>> cert.extensions.get_extension_for_class(x509.BasicConstraints)
<Extension(oid=<ObjectIdentifier(oid=2.5.29.19, name=basicConstraints)>,
critical=True, value=<BasicConstraints(ca=True, path_length=None)>)>
```

class `cryptography.x509.Extension`

New in version 0.9.

oid

Type `ObjectIdentifier`

One of the `ExtensionOID` OIDs.

critical

Type `bool`

Determines whether a given extension is critical or not. [RFC 5280](#) requires that “A certificate-using system MUST reject the certificate if it encounters a critical extension it does not recognize or a critical extension that contains information that it cannot process”.

value

Returns an instance of the extension type corresponding to the OID.

class `cryptography.x509.ExtensionType`

New in version 1.0.

This is the interface against which all the following extension types are registered.

class `cryptography.x509.KeyUsage` (*digital_signature, content_commitment, key_encipherment, data_encipherment, key_agreement, key_cert_sign, crl_sign, encipher_only, decipher_only*)

New in version 0.9.

The key usage extension defines the purpose of the key contained in the certificate. The usage restriction might be employed when a key that could be used for more than one operation is to be restricted.

oid

New in version 1.0.

Type `ObjectIdentifier`

Returns `KEY_USAGE`.

digital_signature**Type** bool

This purpose is set to true when the subject public key is used for verifying digital signatures, other than signatures on certificates (`key_cert_sign`) and CRLs (`crl_sign`).

content_commitment**Type** bool

This purpose is set to true when the subject public key is used for verifying digital signatures, other than signatures on certificates (`key_cert_sign`) and CRLs (`crl_sign`). It is used to provide a non-repudiation service that protects against the signing entity falsely denying some action. In the case of later conflict, a reliable third party may determine the authenticity of the signed data. This was called `non_repudiation` in older revisions of the X.509 specification.

key_encipherment**Type** bool

This purpose is set to true when the subject public key is used for enciphering private or secret keys.

data_encipherment**Type** bool

This purpose is set to true when the subject public key is used for directly enciphering raw user data without the use of an intermediate symmetric cipher.

key_agreement**Type** bool

This purpose is set to true when the subject public key is used for key agreement. For example, when a Diffie-Hellman key is to be used for key management, then this purpose is set to true.

key_cert_sign**Type** bool

This purpose is set to true when the subject public key is used for verifying signatures on public key certificates. If this purpose is set to true then `ca` must be true in the *BasicConstraints* extension.

crl_sign**Type** bool

This purpose is set to true when the subject public key is used for verifying signatures on certificate revocation lists.

encipher_only**Type** bool

When this purposes is set to true and the `key_agreement` purpose is also set, the subject public key may be used only for enciphering data while performing key agreement.

Raises `ValueError` – This is raised if accessed when `key_agreement` is false.

decipher_only**Type** bool

When this purposes is set to true and the `key_agreement` purpose is also set, the subject public key may be used only for deciphering data while performing key agreement.

Raises `ValueError` – This is raised if accessed when `key_agreement` is false.

class `cryptography.x509.BasicConstraints` (*ca*, *path_length*)
New in version 0.9.

Basic constraints is an X.509 extension type that defines whether a given certificate is allowed to sign additional certificates and what path length restrictions may exist.

oid

New in version 1.0.

Type *ObjectIdentifier*

Returns `BASIC_CONSTRAINTS`.

ca

Type `bool`

Whether the certificate can sign certificates.

path_length

Type `int` or `None`

The maximum path length for certificates subordinate to this certificate. This attribute only has meaning if `ca` is true. If `ca` is true then a path length of `None` means there's no restriction on the number of subordinate CAs in the certificate chain. If it is zero or greater then it defines the maximum length for a subordinate CA's certificate chain. For example, a `path_length` of 1 means the certificate can sign a subordinate CA, but the subordinate CA is not allowed to create subordinates with `ca` set to true.

class `cryptography.x509.ExtendedKeyUsage` (*usages*)
New in version 0.9.

This extension indicates one or more purposes for which the certified public key may be used, in addition to or in place of the basic purposes indicated in the key usage extension. The object is iterable to obtain the list of *ExtendedKeyUsageOID* OIDs present.

Parameters *usages* (*list*) – A list of *ExtendedKeyUsageOID* OIDs.

oid

New in version 1.0.

Type *ObjectIdentifier*

Returns `EXTENDED_KEY_USAGE`.

class `cryptography.x509.OCSPNoCheck`
New in version 1.0.

This presence of this extension indicates that an OCSP client can trust a responder for the lifetime of the responder's certificate. CAs issuing such a certificate should realize that a compromise of the responder's key is as serious as the compromise of a CA key used to sign CRLs, at least for the validity period of this certificate. CA's may choose to issue this type of certificate with a very short lifetime and renew it frequently. This extension is only relevant when the certificate is an authorized OCSP responder.

oid

New in version 1.0.

Type *ObjectIdentifier*

Returns `OCSP_NO_CHECK`.

class `cryptography.x509.NameConstraints` (*permitted_subtrees*, *excluded_subtrees*)
New in version 1.0.

The name constraints extension, which only has meaning in a CA certificate, defines a name space within which all subject names in certificates issued beneath the CA certificate must (or must not) be in. For specific details on the way this extension should be processed see [RFC 5280](#).

oid

New in version 1.0.

Type *ObjectIdentifier*

Returns *NAME_CONSTRAINTS*.

permitted_subtrees

Type list of *GeneralName* objects or None

The set of permitted name patterns. If a name matches this and an element in *excluded_subtrees* it is invalid. At least one of *permitted_subtrees* and *excluded_subtrees* will be non-None.

excluded_subtrees

Type list of *GeneralName* objects or None

Any name matching a restriction in the *excluded_subtrees* field is invalid regardless of information appearing in the *permitted_subtrees*. At least one of *permitted_subtrees* and *excluded_subtrees* will be non-None.

class `cryptography.x509.AuthorityKeyIdentifier` (*key_identifier*, *authority_cert_issuer*, *authority_cert_serial_number*)

New in version 0.9.

The authority key identifier extension provides a means of identifying the public key corresponding to the private key used to sign a certificate. This extension is typically used to assist in determining the appropriate certificate chain. For more information about generation and use of this extension see [RFC 5280 section 4.2.1.1](#).

oid

New in version 1.0.

Type *ObjectIdentifier*

Returns *AUTHORITY_KEY_IDENTIFIER*.

key_identifier

Type bytes

A value derived from the public key used to verify the certificate's signature.

authority_cert_issuer

Type *Name* or None

The *Name* of the issuer's issuer.

authority_cert_serial_number

Type int or None

The serial number of the issuer's issuer.

classmethod `from_issuer_public_key` (*public_key*)

New in version 1.0.

Note: This method should be used if the issuer certificate does not contain a *SubjectKeyIdentifier*. Otherwise, use `from_issuer_subject_key_identifier()`.

Creates a new `AuthorityKeyIdentifier` instance using the public key provided to generate the appropriate digest. This should be the **issuer's public key**. The resulting object will contain `key_identifier`, but `authority_cert_issuer` and `authority_cert_serial_number` will be `None`. The generated `key_identifier` is the SHA1 hash of the `subjectPublicKey` ASN.1 bit string. This is the first recommendation in [RFC 5280](#) section 4.2.1.2.

Parameters `public_key` – One of `RSAPublicKey`, `DSAPublicKey`, or `EllipticCurvePublicKey`.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> issuer_cert = x509.load_pem_x509_certificate(pem_data, default_backend())
>>> x509.AuthorityKeyIdentifier.from_issuer_public_key(issuer_cert.public_
↳key())
<AuthorityKeyIdentifier(key_identifier='X\x01\x84
↳$\x1b\xbc+R\x94J=\xa5\x10r\x14Q\xF5\xaf:\xc9', authority_cert_issuer=None,
↳authority_cert_serial_number=None)>
```

classmethod `from_issuer_subject_key_identifier` (`ski`)

New in version 1.3.

Note: This method should be used if the issuer certificate contains a `SubjectKeyIdentifier`. Otherwise, use `from_issuer_public_key()`.

Creates a new `AuthorityKeyIdentifier` instance using the `SubjectKeyIdentifier` from the issuer certificate. The resulting object will contain `key_identifier`, but `authority_cert_issuer` and `authority_cert_serial_number` will be `None`.

Parameters `ski` – The `SubjectKeyIdentifier` from the issuer certificate.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> issuer_cert = x509.load_pem_x509_certificate(pem_data, default_backend())
>>> ski = issuer_cert.extensions.get_extension_for_class(x509.
↳SubjectKeyIdentifier)
>>> x509.AuthorityKeyIdentifier.from_issuer_subject_key_identifier(ski)
<AuthorityKeyIdentifier(key_identifier='X\x01\x84
↳$\x1b\xbc+R\x94J=\xa5\x10r\x14Q\xF5\xaf:\xc9', authority_cert_issuer=None,
↳authority_cert_serial_number=None)>
```

class `cryptography.x509.SubjectKeyIdentifier` (`digest`)

New in version 0.9.

The subject key identifier extension provides a means of identifying certificates that contain a particular public key.

oid

New in version 1.0.

Type `ObjectIdentifier`

Returns `SUBJECT_KEY_IDENTIFIER`.

digest

Type bytes

The binary value of the identifier.

classmethod `from_public_key` (*public_key*)

New in version 1.0.

Creates a new `SubjectKeyIdentifier` instance using the public key provided to generate the appropriate digest. This should be the public key that is in the certificate. The generated digest is the SHA1 hash of the `subjectPublicKey` ASN.1 bit string. This is the first recommendation in [RFC 5280](#) section 4.2.1.2.

Parameters `public_key` – One of `RSAPublicKey`, `DSAPublicKey`, or `EllipticCurvePublicKey`.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> csr = x509.load_pem_x509_csr(pem_req_data, default_backend())
>>> x509.SubjectKeyIdentifier.from_public_key(csr.public_key())
<SubjectKeyIdentifier(digest=
↳ '\xdb\xaa\xf0\x06\x11\xdbD\xfe\xbf\x93\x03\x8av\x88WP7\xa6\x91\xf7')>
```

class `cryptography.x509.SubjectAlternativeName` (*general_names*)

New in version 0.9.

Subject alternative name is an X.509 extension that provides a list of *general name* instances that provide a set of identities for which the certificate is valid. The object is iterable to get every element.

Parameters `general_names` (*list*) – A list of `GeneralName` instances.

oid

New in version 1.0.

Type `ObjectIdentifier`

Returns `SUBJECT_ALTERNATIVE_NAME`.

get_values_for_type (*type*)

Parameters `type` – A `GeneralName` instance. This is one of the *general name classes*.

Returns A list of values extracted from the matched general names. The type of the returned values depends on the `GeneralName`.

```
>>> from cryptography import x509
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> cert = x509.load_pem_x509_certificate(cryptography_cert_pem, default_
↳ backend())
>>> # Get the subjectAltName extension from the certificate
>>> ext = cert.extensions.get_extension_for_oid(ExtensionOID.SUBJECT_
↳ ALTERNATIVE_NAME)
>>> # Get the dNSName entries from the SAN extension
>>> ext.value.get_values_for_type(x509.DNSName)
[u'www.cryptography.io', u'cryptography.io']
```

class `cryptography.x509.IssuerAlternativeName` (*general_names*)

New in version 1.0.

Issuer alternative name is an X.509 extension that provides a list of *general name* instances that provide a set of identities for the certificate issuer. The object is iterable to get every element.

Parameters `general_names` (*list*) – A list of `GeneralName` instances.

oid

New in version 1.0.

Type `ObjectIdentifier`

Returns *ISSUER_ALTERNATIVE_NAME*.

get_values_for_type (*type*)

Parameters *type* – A *GeneralName* instance. This is one of the *general name classes*.

Returns A list of values extracted from the matched general names.

class cryptography.x509.**PrecertificateSignedCertificateTimestamps** (*scts*)
New in version 2.0.

This extension contains *SignedCertificateTimestamp* instances which were issued for the pre-certificate corresponding to this certificate. These can be used to verify that the certificate is included in a public Certificate Transparency log.

It is an iterable containing one or more *SignedCertificateTimestamp* objects.

Parameters *scts* (*list*) – A list of *SignedCertificateTimestamp* objects.

oid

Type *ObjectIdentifier*

Returns *PRECERT_SIGNED_CERTIFICATE_TIMESTAMPS*.

class cryptography.x509.**AuthorityInformationAccess** (*descriptions*)
New in version 0.9.

The authority information access extension indicates how to access information and services for the issuer of the certificate in which the extension appears. Information and services may include online validation services (such as OCSP) and issuer data. It is an iterable, containing one or more *AccessDescription* instances.

Parameters *descriptions* (*list*) – A list of *AccessDescription* objects.

oid

New in version 1.0.

Type *ObjectIdentifier*

Returns *AUTHORITY_INFORMATION_ACCESS*.

class cryptography.x509.**AccessDescription** (*access_method*, *access_location*)
New in version 0.9.

access_method

Type *ObjectIdentifier*

The access method defines what the *access_location* means. It must be either *OCSP* or *CA_ISSUERS*. If it is *OCSP* the access location will be where to obtain OCSP information for the certificate. If it is *CA_ISSUERS* the access location will provide additional information about the issuing certificate.

access_location

Type *GeneralName*

Where to access the information defined by the access method.

class cryptography.x509.**CRLDistributionPoints** (*distribution_points*)
New in version 0.9.

The CRL distribution points extension identifies how CRL information is obtained. It is an iterable, containing one or more *DistributionPoint* instances.

Parameters *distribution_points* (*list*) – A list of *DistributionPoint* instances.

oid

New in version 1.0.

Type *ObjectIdentifier*

Returns *CRL_DISTRIBUTION_POINTS*.

class `cryptography.x509.DistributionPoint` (*full_name, relative_name, reasons, crl_issuer*)

New in version 0.9.

full_name

Type list of *GeneralName* instances or None

This field describes methods to retrieve the CRL. At most one of `full_name` or `relative_name` will be non-None.

relative_name

Type *RelativeDistinguishedName* or None

This field describes methods to retrieve the CRL relative to the CRL issuer. At most one of `full_name` or `relative_name` will be non-None.

Changed in version 1.6: Changed from *Name* to *RelativeDistinguishedName*.

crl_issuer

Type list of *GeneralName* instances or None

Information about the issuer of the CRL.

reasons

Type frozenset of *ReasonFlags* or None

The reasons a given distribution point may be used for when performing revocation checks.

class `cryptography.x509.ReasonFlags`

New in version 0.9.

An enumeration for CRL reasons.

unspecified

It is unspecified why the certificate was revoked. This reason cannot be used as a reason flag in a *DistributionPoint*.

key_compromise

This reason indicates that the private key was compromised.

ca_compromise

This reason indicates that the CA issuing the certificate was compromised.

affiliation_changed

This reason indicates that the subject's name or other information has changed.

superseded

This reason indicates that a certificate has been superseded.

cessation_of_operation

This reason indicates that the certificate is no longer required.

certificate_hold

This reason indicates that the certificate is on hold.

privilege_withdrawn

This reason indicates that the privilege granted by this certificate have been withdrawn.

aa_compromise

When an attribute authority has been compromised.

remove_from_crl

This reason indicates that the certificate was on hold and should be removed from the CRL. This reason cannot be used as a reason flag in a *DistributionPoint*.

class `cryptography.x509.InhibitAnyPolicy` (*skip_certs*)
New in version 1.0.

The `inhibit anyPolicy` extension indicates that the special OID `ANY_POLICY`, is not considered an explicit match for other *CertificatePolicies* except when it appears in an intermediate self-issued CA certificate. The value indicates the number of additional non-self-issued certificates that may appear in the path before `ANY_POLICY` is no longer permitted. For example, a value of one indicates that `ANY_POLICY` may be processed in certificates issued by the subject of this certificate, but not in additional certificates in the path.

oid

New in version 1.0.

Type *ObjectIdentifier*

Returns `INHIBIT_ANY_POLICY`.

skip_certs

Type `int`

class `cryptography.x509.PolicyConstraints`
New in version 1.3.

The policy constraints extension is used to inhibit policy mapping or require that each certificate in a chain contain an acceptable policy identifier. For more information about the use of this extension see [RFC 5280](#).

oid

Type *ObjectIdentifier*

Returns `POLICY_CONSTRAINTS`.

require_explicit_policy

Type `int` or `None`

If this field is not `None`, the value indicates the number of additional certificates that may appear in the chain before an explicit policy is required for the entire path. When an explicit policy is required, it is necessary for all certificates in the chain to contain an acceptable policy identifier in the certificate policies extension. An acceptable policy identifier is the identifier of a policy required by the user of the certification path or the identifier of a policy that has been declared equivalent through policy mapping.

inhibit_policy_mapping

Type `int` or `None`

If this field is not `None`, the value indicates the number of additional certificates that may appear in the chain before policy mapping is no longer permitted. For example, a value of one indicates that policy mapping may be processed in certificates issued by the subject of this certificate, but not in additional certificates in the chain.

class `cryptography.x509.CRLNumber` (*crl_number*)
New in version 1.2.

The CRL number is a CRL extension that conveys a monotonically increasing sequence number for a given CRL scope and CRL issuer. This extension allows users to easily determine when a particular CRL supersedes another CRL. [RFC 5280](#) requires that this extension be present in conforming CRLs.

oid**Type** *ObjectIdentifier*Returns *CRL_NUMBER*.**crl_number****Type** int**class** cryptography.x509.**UnrecognizedExtension**

New in version 1.2.

A generic extension class used to hold the raw value of extensions that cryptography does not know how to parse.

oid**Type** *ObjectIdentifier*

Returns the OID associated with this extension.

value**Type** byte

Returns the DER encoded bytes payload of the extension.

class cryptography.x509.**CertificatePolicies** (*policies*)

New in version 0.9.

The certificate policies extension is an iterable, containing one or more *PolicyInformation* instances.

Parameters *policies* (*list*) – A list of *PolicyInformation* instances.

oid

New in version 1.0.

Type *ObjectIdentifier*Returns *CERTIFICATE_POLICIES*.

Certificate Policies Classes

These classes may be present within a *CertificatePolicies* instance.

class cryptography.x509.**PolicyInformation** (*policy_identifier*, *policy_qualifiers*)

New in version 0.9.

Contains a policy identifier and an optional list of qualifiers.

policy_identifier**Type** *ObjectIdentifier***policy_qualifiers****Type** list

A list consisting of *text* and/or *UserNotice* objects. If the value is text it is a pointer to the practice statement published by the certificate authority. If it is a user notice it is meant for display to the relying party when the certificate is used.

class `cryptography.x509.UserNotice` (*notice_reference*, *explicit_text*)
New in version 0.9.

User notices are intended for display to a relying party when a certificate is used. In practice, few if any UIs expose this data and it is a rarely encoded component.

notice_reference

Type *NoticeReference* or None

The notice reference field names an organization and identifies, by number, a particular statement prepared by that organization.

explicit_text

This field includes an arbitrary textual statement directly in the certificate.

Type *text*

class `cryptography.x509.NoticeReference` (*organization*, *notice_numbers*)

Notice reference can name an organization and provide information about notices related to the certificate. For example, it might identify the organization name and notice number 1. Application software could have a notice file containing the current set of notices for the named organization; the application would then extract the notice text from the file and display it. In practice this is rarely seen.

New in version 0.9.

organization

Type *text*

notice_numbers

Type list

A list of integers.

CRL Entry Extensions

These extensions are only valid within a *RevokedCertificate* object.

class `cryptography.x509.CertificateIssuer` (*general_names*)
New in version 1.2.

The certificate issuer is an extension that is only valid inside *RevokedCertificate* objects. If the `indirectCRL` property of the parent CRL's `IssuingDistributionPoint` extension is set, then this extension identifies the certificate issuer associated with the revoked certificate. The object is iterable to get every element.

Parameters `general_names` (*list*) – A list of *GeneralName* instances.

oid

Type *ObjectIdentifier*

Returns `CERTIFICATE_ISSUER`.

get_values_for_type (*type*)

Parameters `type` – A *GeneralName* instance. This is one of the *general name classes*.

Returns A list of values extracted from the matched general names. The type of the returned values depends on the *GeneralName*.

class `cryptography.x509.CRLReason` (*reason*)
 New in version 1.2.

CRL reason (also known as `reasonCode`) is an extension that is only valid inside *RevokedCertificate* objects. It identifies a reason for the certificate revocation.

Parameters `reason` – A value from the *CRLEntryExtensionOID* enum.

oid

Type *ObjectIdentifier*

Returns *CRL_REASON*.

reason

Type An element from *ReasonFlags*

class `cryptography.x509.InvalidityDate` (*invalidity_date*)
 New in version 1.2.

Invalidity date is an extension that is only valid inside *RevokedCertificate* objects. It provides the date on which it is known or suspected that the private key was compromised or that the certificate otherwise became invalid. This date may be earlier than the revocation date in the CRL entry, which is the date at which the CA processed the revocation.

Parameters `invalidity_date` – The `datetime.datetime` when it is known or suspected that the private key was compromised.

oid

Type *ObjectIdentifier*

Returns *INVALIDITY_DATE*.

invalidity_date

Type `datetime.datetime`

Object Identifiers

X.509 elements are frequently identified by *ObjectIdentifier* instances. The following common OIDs are available as constants.

class `cryptography.x509.oid.NameOID`
 These OIDs are typically seen in X.509 names.

New in version 1.0.

COMMON_NAME

Corresponds to the dotted string "2.5.4.3". Historically the domain name would be encoded here for server certificates. **RFC 2818** deprecates this practice and names of that type should now be located in a *SubjectAlternativeName* extension.

COUNTRY_NAME

Corresponds to the dotted string "2.5.4.6".

LOCALITY_NAME

Corresponds to the dotted string "2.5.4.7".

STATE_OR_PROVINCE_NAME

Corresponds to the dotted string "2.5.4.8".

STREET_ADDRESS

New in version 1.6.

Corresponds to the dotted string "2.5.4.9".

ORGANIZATION_NAME

Corresponds to the dotted string "2.5.4.10".

ORGANIZATIONAL_UNIT_NAME

Corresponds to the dotted string "2.5.4.11".

SERIAL_NUMBER

Corresponds to the dotted string "2.5.4.5". This is distinct from the serial number of the certificate itself (which can be obtained with `serial_number()`).

SURNAME

Corresponds to the dotted string "2.5.4.4".

GIVEN_NAME

Corresponds to the dotted string "2.5.4.42".

TITLE

Corresponds to the dotted string "2.5.4.12".

GENERATION_QUALIFIER

Corresponds to the dotted string "2.5.4.44".

X500_UNIQUE_IDENTIFIER

New in version 1.6.

Corresponds to the dotted string "2.5.4.45".

DN_QUALIFIER

Corresponds to the dotted string "2.5.4.46". This specifies disambiguating information to add to the relative distinguished name of an entry. See [RFC 2256](#).

PSEUDONYM

Corresponds to the dotted string "2.5.4.65".

USER_ID

New in version 1.6.

Corresponds to the dotted string "0.9.2342.19200300.100.1.1".

DOMAIN_COMPONENT

Corresponds to the dotted string "0.9.2342.19200300.100.1.25". A string holding one component of a domain name. See [RFC 4519](#).

EMAIL_ADDRESS

Corresponds to the dotted string "1.2.840.113549.1.9.1".

JURISDICTION_COUNTRY_NAME

Corresponds to the dotted string "1.3.6.1.4.1.311.60.2.1.3".

JURISDICTION_LOCALITY_NAME

Corresponds to the dotted string "1.3.6.1.4.1.311.60.2.1.1".

JURISDICTION_STATE_OR_PROVINCE_NAME

Corresponds to the dotted string "1.3.6.1.4.1.311.60.2.1.2".

BUSINESS_CATEGORY

Corresponds to the dotted string "2.5.4.15".

POSTAL_ADDRESS

New in version 1.6.

Corresponds to the dotted string "2.5.4.16".

POSTAL_CODE

New in version 1.6.

Corresponds to the dotted string "2.5.4.17".

class cryptography.x509.oid.**SignatureAlgorithmOID**

New in version 1.0.

RSA_WITH_MD5

Corresponds to the dotted string "1.2.840.113549.1.1.4". This is an MD5 digest signed by an RSA key.

RSA_WITH_SHA1

Corresponds to the dotted string "1.2.840.113549.1.1.5". This is a SHA1 digest signed by an RSA key.

RSA_WITH_SHA224

Corresponds to the dotted string "1.2.840.113549.1.1.14". This is a SHA224 digest signed by an RSA key.

RSA_WITH_SHA256

Corresponds to the dotted string "1.2.840.113549.1.1.11". This is a SHA256 digest signed by an RSA key.

RSA_WITH_SHA384

Corresponds to the dotted string "1.2.840.113549.1.1.12". This is a SHA384 digest signed by an RSA key.

RSA_WITH_SHA512

Corresponds to the dotted string "1.2.840.113549.1.1.13". This is a SHA512 digest signed by an RSA key.

ECDSA_WITH_SHA1

Corresponds to the dotted string "1.2.840.10045.4.1". This is a SHA1 digest signed by an ECDSA key.

ECDSA_WITH_SHA224

Corresponds to the dotted string "1.2.840.10045.4.3.1". This is a SHA224 digest signed by an ECDSA key.

ECDSA_WITH_SHA256

Corresponds to the dotted string "1.2.840.10045.4.3.2". This is a SHA256 digest signed by an ECDSA key.

ECDSA_WITH_SHA384

Corresponds to the dotted string "1.2.840.10045.4.3.3". This is a SHA384 digest signed by an ECDSA key.

ECDSA_WITH_SHA512

Corresponds to the dotted string "1.2.840.10045.4.3.4". This is a SHA512 digest signed by an ECDSA key.

DSA_WITH_SHA1

Corresponds to the dotted string "1.2.840.10040.4.3". This is a SHA1 digest signed by a DSA key.

DSA_WITH_SHA224

Corresponds to the dotted string "2.16.840.1.101.3.4.3.1". This is a SHA224 digest signed by a DSA key.

DSA_WITH_SHA256

Corresponds to the dotted string "2.16.840.1.101.3.4.3.2". This is a SHA256 digest signed by a DSA key.

class cryptography.x509.oid.**ExtendedKeyUsageOID**

New in version 1.0.

SERVER_AUTH

Corresponds to the dotted string "1.3.6.1.5.5.7.3.1". This is used to denote that a certificate may be used for TLS web server authentication.

CLIENT_AUTH

Corresponds to the dotted string "1.3.6.1.5.5.7.3.2". This is used to denote that a certificate may be used for TLS web client authentication.

CODE_SIGNING

Corresponds to the dotted string "1.3.6.1.5.5.7.3.3". This is used to denote that a certificate may be used for code signing.

EMAIL_PROTECTION

Corresponds to the dotted string "1.3.6.1.5.5.7.3.4". This is used to denote that a certificate may be used for email protection.

TIME_STAMPING

Corresponds to the dotted string "1.3.6.1.5.5.7.3.8". This is used to denote that a certificate may be used for time stamping.

OCSP_SIGNING

Corresponds to the dotted string "1.3.6.1.5.5.7.3.9". This is used to denote that a certificate may be used for signing OCSP responses.

class cryptography.x509.oid.**AuthorityInformationAccessOID**

New in version 1.0.

OCSP

Corresponds to the dotted string "1.3.6.1.5.5.7.48.1". Used as the identifier for OCSP data in *AccessDescription* objects.

CA_ISSUERS

Corresponds to the dotted string "1.3.6.1.5.5.7.48.2". Used as the identifier for CA issuer data in *AccessDescription* objects.

class cryptography.x509.oid.**CertificatePoliciesOID**

New in version 1.0.

CPS_QUALIFIER

Corresponds to the dotted string "1.3.6.1.5.5.7.2.1".

CPS_USER_NOTICE

Corresponds to the dotted string "1.3.6.1.5.5.7.2.2".

ANY_POLICY

Corresponds to the dotted string "2.5.29.32.0".

class cryptography.x509.oid.**ExtensionOID**

New in version 1.0.

BASIC_CONSTRAINTS

Corresponds to the dotted string "2.5.29.19". The identifier for the *BasicConstraints* extension type.

KEY_USAGE

Corresponds to the dotted string "2.5.29.15". The identifier for the *KeyUsage* extension type.

SUBJECT_ALTERNATIVE_NAME

Corresponds to the dotted string "2.5.29.17". The identifier for the *SubjectAlternativeName* extension type.

ISSUER_ALTERNATIVE_NAME

Corresponds to the dotted string "2.5.29.18". The identifier for the *IssuerAlternativeName* extension type.

SUBJECT_KEY_IDENTIFIER

Corresponds to the dotted string "2.5.29.14". The identifier for the *SubjectKeyIdentifier* extension type.

NAME_CONSTRAINTS

Corresponds to the dotted string "2.5.29.30". The identifier for the *NameConstraints* extension type.

CRL_DISTRIBUTION_POINTS

Corresponds to the dotted string "2.5.29.31". The identifier for the *CRLDistributionPoints* extension type.

CERTIFICATE_POLICIES

Corresponds to the dotted string "2.5.29.32". The identifier for the *CertificatePolicies* extension type.

AUTHORITY_KEY_IDENTIFIER

Corresponds to the dotted string "2.5.29.35". The identifier for the *AuthorityKeyIdentifier* extension type.

EXTENDED_KEY_USAGE

Corresponds to the dotted string "2.5.29.37". The identifier for the *ExtendedKeyUsage* extension type.

AUTHORITY_INFORMATION_ACCESS

Corresponds to the dotted string "1.3.6.1.5.5.7.1.1". The identifier for the *AuthorityInformationAccess* extension type.

INHIBIT_ANY_POLICY

Corresponds to the dotted string "2.5.29.54". The identifier for the *InhibitAnyPolicy* extension type.

OCSP_NO_CHECK

Corresponds to the dotted string "1.3.6.1.5.5.7.48.1.5". The identifier for the *OCSPNoCheck* extension type.

CRL_NUMBER

Corresponds to the dotted string "2.5.29.20". The identifier for the *CRLNumber* extension type. This extension only has meaning for certificate revocation lists.

PRECERT_SIGNED_CERTIFICATE_TIMESTAMPS

New in version 1.9.

Corresponds to the dotted string "1.3.6.1.4.1.11129.2.4.2".

POLICY_CONSTRAINTS

Corresponds to the dotted string "2.5.29.36". The identifier for the *PolicyConstraints* extension type.

class `cryptography.x509.oid.CRLEntryExtensionOID`
New in version 1.2.

CERTIFICATE_ISSUER

Corresponds to the dotted string "2.5.29.29".

CRL_REASON

Corresponds to the dotted string "2.5.29.21".

INVALIDITY_DATE

Corresponds to the dotted string "2.5.29.24".

Helper Functions

`cryptography.x509.random_serial_number()`
New in version 1.6.

Generates a random serial number suitable for use when constructing certificates.

Exceptions

class `cryptography.x509.InvalidVersion`
This is raised when an X.509 certificate has an invalid version number.

parsed_version

Type `int`

Returns the raw version that was parsed from the certificate.

class `cryptography.x509.DuplicateExtension`
This is raised when more than one X.509 extension of the same type is found within a certificate.

oid

Type *ObjectIdentifier*

Returns the OID.

class `cryptography.x509.ExtensionNotFound`
This is raised when calling *Extensions.get_extension_for_oid()* with an extension OID that is not present in the certificate.

oid

Type *ObjectIdentifier*

Returns the OID.

class `cryptography.x509.UnsupportedGeneralNameType`
This is raised when a certificate contains an unsupported general name type in an extension.

type

Type `int`

The integer value of the unsupported type. The complete list of types can be found in RFC 5280 section 4.2.1.6.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Primitives

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Authenticated encryption

Authenticated encryption with associated data (AEAD) are encryption schemes which provide both confidentiality and integrity for their ciphertext. They also support providing integrity for associated data which is not encrypted.

class `cryptography.hazmat.primitives.ciphers.aead.ChaCha20Poly1305` (*key*)
 New in version 2.0.

The ChaCha20Poly1305 construction is defined in [RFC 7539](#) section 2.8. It is a stream cipher combined with a MAC that offers strong integrity guarantees.

Parameters *key* (*bytes*) – A 32-byte key. This **must** be kept secret.

Raises `cryptography.exceptions.UnsupportedAlgorithm` – If the version of OpenSSL does not support ChaCha20Poly1305.

```
>>> import os
>>> from cryptography.hazmat.primitives.ciphers.aead import ChaCha20Poly1305
>>> data = b"a secret message"
>>> aad = b"authenticated but unencrypted data"
>>> key = ChaCha20Poly1305.generate_key()
>>> chacha = ChaCha20Poly1305(key)
>>> nonce = os.urandom(12)
>>> ct = chacha.encrypt(nonce, data, aad)
>>> chacha.decrypt(nonce, ct, aad)
'a secret message'
```

classmethod `generate_key` ()

Securely generates a random ChaCha20Poly1305 key.

Returns bytes A 32 byte key.

encrypt (*nonce*, *data*, *associated_data*)

Warning: Reuse of a nonce with a given key compromises the security of any message with that nonce and key pair.

Encrypts the *data* provided and authenticates the *associated_data*. The output of this can be passed directly to the `decrypt` method.

Parameters

- **nonce** (*bytes*) – A 12 byte value. **NEVER REUSE A NONCE** with a key.
- **data** (*bytes*) – The data to encrypt.
- **associated_data** (*bytes*) – Additional data that should be authenticated with the key, but does not need to be encrypted. Can be `None`.

Returns bytes The ciphertext bytes with the 16 byte tag appended.

decrypt (*nonce, data, associated_data*)

Decrypts the `data` and authenticates the `associated_data`. If you called `encrypt` with `associated_data` you must pass the same `associated_data` in `decrypt` or the integrity check will fail.

Parameters

- **nonce** (*bytes*) – A 12 byte value. **NEVER REUSE A NONCE** with a key.
- **data** (*bytes*) – The data to decrypt (with tag appended).
- **associated_data** (*bytes*) – Additional data to authenticate. Can be `None` if none was passed during encryption.

Returns bytes The original plaintext.

Raises `cryptography.exceptions.InvalidTag` – If the authentication tag doesn't validate this exception will be raised. This will occur when the ciphertext has been changed, but will also occur when the key, nonce, or associated data are wrong.

This is a “Hazardous Materials” module. You should **ONLY** use it if you're 100% absolutely sure that you know what you're doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Asymmetric algorithms

Asymmetric cryptography is a branch of cryptography where a secret key can be divided into two parts, a *public key* and a *private key*. The public key can be given to anyone, trusted or not, while the private key must be kept secret (just like the key in symmetric cryptography).

Asymmetric cryptography has two primary use cases: authentication and confidentiality. Using asymmetric cryptography, messages can be signed with a private key, and then anyone with the public key is able to verify that the message was created by someone possessing the corresponding private key. This can be combined with a *proof of identity* system to know what entity (person or group) actually owns that private key, providing authentication.

Encryption with asymmetric cryptography works in a slightly different way from symmetric encryption. Someone with the public key is able to encrypt a message, providing confidentiality, and then only the person in possession of the private key is able to decrypt it.

This is a “Hazardous Materials” module. You should **ONLY** use it if you're 100% absolutely sure that you know what you're doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

DSA

DSA is a *public-key* algorithm for signing messages.

Generation

`cryptography.hazmat.primitives.asymmetric.dsa.generate_private_key` (*key_size*,
backend)

New in version 0.5.

Generate a DSA private key from the given key size. This function will generate a new set of parameters and key in one step.

Parameters

- **key_size** (*int*) – The length of the modulus in bits. It should be either 1024, 2048 or 3072. For keys generated in 2015 this should be at least 2048 (See page 41). Note that some applications (such as SSH) have not yet gained support for larger key sizes specified in FIPS 186-3 and are still restricted to only the 1024-bit keys specified in FIPS 186-2.
- **backend** – An instance of *DSABackend*.

Returns An instance of *DSAPrivateKey*.

Raises *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *DSABackend*

`cryptography.hazmat.primitives.asymmetric.dsa.generate_parameters` (*key_size*,
backend)

New in version 0.5.

Generate DSA parameters using the provided backend.

Parameters

- **key_size** (*int*) – The length of *q*. It should be either 1024, 2048 or 3072. For keys generated in 2015 this should be at least 2048 (See page 41). Note that some applications (such as SSH) have not yet gained support for larger key sizes specified in FIPS 186-3 and are still restricted to only the 1024-bit keys specified in FIPS 186-2.
- **backend** – An instance of *DSABackend*.

Returns An instance of *DSAParameters*.

Raises *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *DSABackend*

Signing

Using a *DSAPrivateKey* instance.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.asymmetric import dsa
>>> private_key = dsa.generate_private_key(
...     key_size=1024,
...     backend=default_backend()
... )
>>> data = b"this is some data I'd like to sign"
>>> signature = private_key.sign(
...     data,
...     hashes.SHA256()
... )
```

The signature is a bytes object, whose contents is DER encoded as described in [RFC 3279](#). This can be decoded using `decode_dss_signature()`.

If your data is too large to be passed in a single call, you can hash it separately and pass that value using `Prehashed`.

```
>>> from cryptography.hazmat.primitives.asymmetric import utils
>>> chosen_hash = hashes.SHA256()
>>> hasher = hashes.Hash(chosen_hash, default_backend())
>>> hasher.update(b"data & ")
>>> hasher.update(b"more data")
>>> digest = hasher.finalize()
>>> sig = private_key.sign(
...     digest,
...     utils.Prehashed(chosen_hash)
... )
```

Verification

Verification is performed using a `DSAPublicKey` instance. You can get a public key object with `load_pem_public_key()`, `load_der_public_key()`, `public_key()`, or `public_key()`.

```
>>> public_key = private_key.public_key()
>>> public_key.verify(
...     signature,
...     data,
...     hashes.SHA256()
... )
```

`verify()` takes the signature in the same format as is returned by `sign()`.

`verify()` will raise an `InvalidSignature` exception if the signature isn't valid.

If your data is too large to be passed in a single call, you can hash it separately and pass that value using `Prehashed`.

```
>>> chosen_hash = hashes.SHA256()
>>> hasher = hashes.Hash(chosen_hash, default_backend())
>>> hasher.update(b"data & ")
>>> hasher.update(b"more data")
>>> digest = hasher.finalize()
>>> public_key.verify(
...     sig,
...     digest,
...     utils.Prehashed(chosen_hash)
... )
```

Numbers

class `cryptography.hazmat.primitives.asymmetric.dsa.DSAPparameterNumbers` (p , q , g)

New in version 0.5.

The collection of integers that make up a set of DSA parameters.

P

Type int

The public modulus.

q

Type int

The sub-group order.

g

Type int

The generator.

parameters (*backend*)

Parameters *backend* – An instance of *DSABackend*.

Returns A new instance of *DSAParameters*.

class cryptography.hazmat.primitives.asymmetric.dsa.**DSAPublicNumbers** (*y*, *parameter_numbers*)

New in version 0.5.

The collection of integers that make up a DSA public key.

y

Type int

The public value *y*.

parameter_numbers

Type *DSAParameterNumbers*

The *DSAParameterNumbers* associated with the public key.

public_key (*backend*)

Parameters *backend* – An instance of *DSABackend*.

Returns A new instance of *DSAPublicKey*.

class cryptography.hazmat.primitives.asymmetric.dsa.**DSAPrivateNumbers** (*x*, *public_numbers*)

New in version 0.5.

The collection of integers that make up a DSA private key.

Warning: Revealing the value of *x* will compromise the security of any cryptographic operations performed.

x

Type int

The private value *x*.

public_numbers

Type *DSAPublicNumbers*

The *DSAPublicNumbers* associated with the private key.

private_key (*backend*)

Parameters *backend* – An instance of *DSABackend*.

Returns A new instance of *DSAPrivateKey*.

Key interfaces

class `cryptography.hazmat.primitives.asymmetric.dsa.DSAParameters`

New in version 0.3.

DSA parameters.

generate_private_key ()

New in version 0.5.

Generate a DSA private key. This method can be used to generate many new private keys from a single set of parameters.

Returns An instance of *DSAPrivateKey*.

class `cryptography.hazmat.primitives.asymmetric.dsa.DSAParametersWithNumbers`

New in version 0.5.

Extends *DSAParameters*.

parameter_numbers ()

Create a *DSAParameterNumbers* object.

Returns A *DSAParameterNumbers* instance.

class `cryptography.hazmat.primitives.asymmetric.dsa.DSAPrivateKey`

New in version 0.3.

A DSA private key.

public_key ()

Returns *DSAPublicKey*

An DSA public key object corresponding to the values of the private key.

parameters ()

Returns *DSAParameters*

The DSAParameters object associated with this private key.

key_size

Type int

The bit length of *q*.

sign (*data*, *algorithm*)

New in version 1.5.

Changed in version 1.6: *Prehashed* can now be used as an algorithm.

Sign one block of data which can be verified later by others using the public key.

Parameters

- **data** (*bytes*) – The message string to sign.
- **algorithm** – An instance of *HashAlgorithm* or *Prehashed* if the data you want to sign has already been hashed.

Return bytes Signature.

class `cryptography.hazmat.primitives.asymmetric.dsa.DSAPrivateKeyWithSerialization`
New in version 0.8.

Extends `DSAPrivateKey`.

private_numbers ()

Create a `DSAPrivateNumbers` object.

Returns A `DSAPrivateNumbers` instance.

private_bytes (*encoding, format, encryption_algorithm*)

Allows serialization of the key to bytes. Encoding (`PEM` or `DER`), format (`TraditionalOpenSSL` or `PKCS8`) and encryption algorithm (such as `BestAvailableEncryption` or `NoEncryption`) are chosen to define the exact serialization.

Parameters

- **encoding** – A value from the `Encoding` enum.
- **format** – A value from the `PrivateFormat` enum.
- **encryption_algorithm** – An instance of an object conforming to the `KeySerializationEncryption` interface.

Return bytes Serialized key.

class `cryptography.hazmat.primitives.asymmetric.dsa.DSAPublicKey`
New in version 0.3.

A DSA public key.

key_size

Type `int`

The bit length of q .

parameters ()

Returns `DSAParameters`

The `DSAParameters` object associated with this public key.

public_numbers ()

Create a `DSAPublicNumbers` object.

Returns A `DSAPublicNumbers` instance.

public_bytes (*encoding, format*)

Allows serialization of the key to bytes. Encoding (`PEM` or `DER`) and format (`SubjectPublicKeyInfo`) are chosen to define the exact serialization.

Parameters

- **encoding** – A value from the `Encoding` enum.
- **format** – A value from the `PublicFormat` enum.

Return bytes Serialized key.

verify (*signature, data, algorithm*)

New in version 1.5.

Changed in version 1.6: `Prehashed` can now be used as an algorithm.

Verify one block of data was signed by the private key associated with this public key.

Parameters

- **signature** (*bytes*) – The signature to verify.
- **data** (*bytes*) – The message string that was signed.
- **algorithm** – An instance of *HashAlgorithm* or *Prehashed* if the data you want to sign has already been hashed.

Raises *cryptography.exceptions.InvalidSignature* – If the signature does not validate.

class `cryptography.hazmat.primitives.asymmetric.dsa.DSAPublicKeyWithSerialization`
New in version 0.8.

Alias for *DSAPublicKey*.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Elliptic curve cryptography

`cryptography.hazmat.primitives.asymmetric.ec.generate_private_key` (*curve*, *backend*)

New in version 0.5.

Generate a new private key on *curve* for use with *backend*.

Parameters

- **curve** – An instance of *EllipticCurve*.
- **backend** – An instance of *EllipticCurveBackend*.

Returns A new instance of *EllipticCurvePrivateKey*.

`cryptography.hazmat.primitives.asymmetric.ec.derive_private_key` (*private_value*,
curve, *backend*)

New in version 1.6.

Derive a private key from *private_value* on *curve* for use with *backend*.

Parameters

- **private_value** (*int*) – The secret scalar value.
- **curve** – An instance of *EllipticCurve*.
- **backend** – An instance of *EllipticCurveBackend*.

Returns A new instance of *EllipticCurvePrivateKey*.

Elliptic Curve Signature Algorithms

class `cryptography.hazmat.primitives.asymmetric.ec.ECDSA` (*algorithm*)
New in version 0.5.

The ECDSA signature algorithm first standardized in NIST publication [FIPS 186-3](#), and later in [FIPS 186-4](#).

Parameters **algorithm** – An instance of *HashAlgorithm*.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.asymmetric import ec
>>> private_key = ec.generate_private_key(
...     ec.SECP384R1(), default_backend()
... )
>>> data = b"this is some data I'd like to sign"
>>> signature = private_key.sign(
...     data,
...     ec.ECDSA(hashes.SHA256())
... )
```

The signature is a bytes object, whose contents is DER encoded as described in [RFC 3279](#). This can be decoded using `decode_dss_signature()`.

If your data is too large to be passed in a single call, you can hash it separately and pass that value using `Prehashed`.

```
>>> from cryptography.hazmat.primitives.asymmetric import utils
>>> chosen_hash = hashes.SHA256()
>>> hasher = hashes.Hash(chosen_hash, default_backend())
>>> hasher.update(b"data & ")
>>> hasher.update(b"more data")
>>> digest = hasher.finalize()
>>> sig = private_key.sign(
...     digest,
...     ec.ECDSA(utils.Prehashed(chosen_hash))
... )
```

Verification requires the public key, the signature itself, the signed data, and knowledge of the hashing algorithm that was used when producing the signature:

```
>>> public_key = private_key.public_key()
>>> public_key.verify(signature, data, ec.ECDSA(hashes.SHA256()))
```

If the signature is not valid, an `InvalidSignature` exception will be raised.

If your data is too large to be passed in a single call, you can hash it separately and pass that value using `Prehashed`.

```
>>> chosen_hash = hashes.SHA256()
>>> hasher = hashes.Hash(chosen_hash, default_backend())
>>> hasher.update(b"data & ")
>>> hasher.update(b"more data")
>>> digest = hasher.finalize()
>>> public_key.verify(
...     sig,
...     digest,
...     ec.ECDSA(utils.Prehashed(chosen_hash))
... )
```

Note: Although in this case the public key was derived from the private one, in a typical setting you will not possess the private key. The [Key loading](#) section explains how to load the public key from other sources.

`class cryptography.hazmat.primitives.asymmetric.ec.EllipticCurvePrivateNumbers` (*private_value*, *public_numbers*)

New in version 0.5.

The collection of integers that make up an EC private key.

public_numbers

Type *EllipticCurvePublicNumbers*

The *EllipticCurvePublicNumbers* which makes up the EC public key associated with this EC private key.

private_value

Type int

The private value.

private_key (*backend*)

Convert a collection of numbers into a private key suitable for doing actual cryptographic operations.

Parameters **backend** – An instance of *EllipticCurveBackend*.

Returns A new instance of *EllipticCurvePrivateKey*.

```
class cryptography.hazmat.primitives.asymmetric.ec.EllipticCurvePublicNumbers (x,
                                                                    y,
                                                                    curve)
```

New in version 0.5.

The collection of integers that make up an EC public key.

curve

Type *EllipticCurve*

The elliptic curve for this key.

x

Type int

The affine x component of the public point used for verifying.

y

Type int

The affine y component of the public point used for verifying.

public_key (*backend*)

Convert a collection of numbers into a public key suitable for doing actual cryptographic operations.

Parameters **backend** – An instance of *EllipticCurveBackend*.

Returns A new instance of *EllipticCurvePublicKey*.

encode_point ()

New in version 1.1.

Encodes an elliptic curve point to a byte string as described in [SEC 1 v2.0 section 2.3.3](#). This method only supports uncompressed points.

Return bytes The encoded point.

classmethod from_encoded_point (*curve, data*)

New in version 1.1.

Decodes a byte string as described in [SEC 1 v2.0 section 2.3.3](#) and returns an *EllipticCurvePublicNumbers*. This method only supports uncompressed points.

Parameters

- **curve** – An *EllipticCurve* instance.
- **data** (*bytes*) – The serialized point byte string.

Returns An *EllipticCurvePublicNumbers* instance.

Raises

- **ValueError** – Raised on invalid point type or data length.
- **TypeError** – Raised when curve is not an *EllipticCurve*.

Elliptic Curve Key Exchange algorithm

class `cryptography.hazmat.primitives.asymmetric.ec.ECDH`
New in version 1.1.

The Elliptic Curve Diffie-Hellman Key Exchange algorithm first standardized in NIST publication 800-56A, and later in 800-56Ar2.

For most applications the `shared_key` should be passed to a key derivation function.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives.asymmetric import ec
>>> # Generate a private key for use in the exchange.
>>> private_key = ec.generate_private_key(
...     ec.SECP384R1(), default_backend()
... )
>>> # In a real handshake the peer_public_key will be received from the
>>> # other party. For this example we'll generate another private key
>>> # and get a public key from that.
>>> peer_public_key = ec.generate_private_key(
...     ec.SECP384R1(), default_backend()
... ).public_key()
>>> shared_key = private_key.exchange(ec.ECDH(), peer_public_key)
>>> # For the next handshake we MUST generate another private key.
>>> private_key_2 = ec.generate_private_key(
...     ec.SECP384R1(), default_backend()
... )
>>> peer_public_key_2 = ec.generate_private_key(
...     ec.SECP384R1(), default_backend()
... ).public_key()
>>> shared_key_2 = private_key_2.exchange(ec.ECDH(), peer_public_key_2)
```

ECDHE (or EECDH), the ephemeral form of this exchange, is **strongly preferred** over simple ECDH and provides *forward secrecy* when used. You must generate a new private key using `generate_private_key()` for each `exchange()` when performing an ECDHE key exchange.

Elliptic Curves

Elliptic curves provide equivalent security at much smaller key sizes than other asymmetric cryptography systems such as RSA or DSA. For many operations elliptic curves are also significantly faster; *elliptic curve diffie-hellman is faster than diffie-hellman*.

Note: Curves with a size of *less than 224 bits* should not be used. You should strongly consider using curves of at least 224 bits.

Generally the NIST prime field (“P”) curves are significantly faster than the other types suggested by NIST at both signing and verifying with ECDSA.

Prime fields also *minimize the number of security concerns for elliptic-curve cryptography*. However, there is *some concern* that both the prime field and binary field (“B”) NIST curves may have been weakened during their generation.

Currently *cryptography* only supports NIST curves, none of which are considered “safe” by the *SafeCurves* project run by Daniel J. Bernstein and Tanja Lange.

All named curves are instances of *EllipticCurve*.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT571K1`
New in version 0.5.

SECG curve `sect571k1`. Also called NIST K-571.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT409K1`
New in version 0.5.

SECG curve `sect409k1`. Also called NIST K-409.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT283K1`
New in version 0.5.

SECG curve `sect283k1`. Also called NIST K-283.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT233K1`
New in version 0.5.

SECG curve `sect233k1`. Also called NIST K-233.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT163K1`
New in version 0.5.

SECG curve `sect163k1`. Also called NIST K-163.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT571R1`
New in version 0.5.

SECG curve `sect571r1`. Also called NIST B-571.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT409R1`
New in version 0.5.

SECG curve `sect409r1`. Also called NIST B-409.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT283R1`
New in version 0.5.

SECG curve `sect283r1`. Also called NIST B-283.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT233R1`
New in version 0.5.

SECG curve `sect233r1`. Also called NIST B-233.

class `cryptography.hazmat.primitives.asymmetric.ec.SECT163R2`
New in version 0.5.

SECG curve `sect163r2`. Also called NIST B-163.

class `cryptography.hazmat.primitives.asymmetric.ec.SECP521R1`
New in version 0.5.

SECG curve `secp521r1`. Also called NIST P-521.

class `cryptography.hazmat.primitives.asymmetric.ec.SECP384R1`
New in version 0.5.

SECG curve `secp384r1`. Also called NIST P-384.

class `cryptography.hazmat.primitives.asymmetric.ec.SECP256R1`
New in version 0.5.

SECG curve `secp256r1`. Also called NIST P-256.

class `cryptography.hazmat.primitives.asymmetric.ec.SECP224R1`
New in version 0.5.

SECG curve `secp224r1`. Also called NIST P-224.

class `cryptography.hazmat.primitives.asymmetric.ec.SECP192R1`
New in version 0.5.

SECG curve `secp192r1`. Also called NIST P-192.

class `cryptography.hazmat.primitives.asymmetric.ec.SECP256K1`
New in version 0.9.

SECG curve `secp256k1`.

Key Interfaces

class `cryptography.hazmat.primitives.asymmetric.ec.EllipticCurve`
New in version 0.5.

A named elliptic curve.

name

Type string

The name of the curve. Usually the name used for the ASN.1 OID such as `secp256k1`.

key_size

Type int

Size (in bits) of a secret scalar for the curve (as generated by `generate_private_key()`).

class `cryptography.hazmat.primitives.asymmetric.ec.EllipticCurveSignatureAlgorithm`
New in version 0.5.

Changed in version 1.6: *Prehashed* can now be used as an algorithm.

A signature algorithm for use with elliptic curve keys.

algorithm

Type *HashAlgorithm* or *Prehashed*

The digest algorithm to be used with the signature scheme.

class `cryptography.hazmat.primitives.asymmetric.ec.EllipticCurvePrivateKey`
New in version 0.5.

An elliptic curve private key for use with an algorithm such as *ECDSA* or *EdDSA*.

exchange (*algorithm, peer_public_key*)

New in version 1.1.

Performs a key exchange operation using the provided algorithm with the peer's public key.

For most applications the result should be passed to a key derivation function.

Parameters

- **algorithm** – The key exchange algorithm, currently only *ECDH* is supported.
- **peer_public_key** (*EllipticCurvePublicKey*) – The public key for the peer.

Returns bytes A shared key.

public_key ()

Returns *EllipticCurvePublicKey*

The *EllipticCurvePublicKey* object for this private key.

sign (*data, signature_algorithm*)

New in version 1.5.

Sign one block of data which can be verified later by others using the public key.

Parameters

- **data** (*bytes*) – The message string to sign.
- **signature_algorithm** – An instance of *EllipticCurveSignatureAlgorithm*, such as *ECDSA*.

Return bytes Signature.

key_size

New in version 1.9.

Type int

Size (in bits) of a secret scalar for the curve (as generated by *generate_private_key*()).

class `cryptography.hazmat.primitives.asymmetric.ec.EllipticCurvePrivateKeyWithSerialization`
New in version 0.8.

Extends *EllipticCurvePrivateKey*.

private_numbers ()

Create a *EllipticCurvePrivateNumbers* object.

Returns An *EllipticCurvePrivateNumbers* instance.

private_bytes (*encoding, format, encryption_algorithm*)

Allows serialization of the key to bytes. Encoding (*PEM* or *DER*), format (*TraditionalOpenSSL* or *PKCS8*) and encryption algorithm (such as *BestAvailableEncryption* or *NoEncryption*) are chosen to define the exact serialization.

Parameters

- **encoding** – A value from the *Encoding* enum.
- **format** – A value from the *PrivateFormat* enum.
- **encryption_algorithm** – An instance of an object conforming to the *KeySerializationEncryption* interface.

Return bytes Serialized key.

class `cryptography.hazmat.primitives.asymmetric.ec.EllipticCurvePublicKey`
 New in version 0.5.

An elliptic curve public key.

curve

Type `EllipticCurve`

The elliptic curve for this key.

public_numbers ()

Create a `EllipticCurvePublicNumbers` object.

Returns An `EllipticCurvePublicNumbers` instance.

public_bytes (*encoding, format*)

Allows serialization of the key to bytes. Encoding (`PEM` or `DER`) and format (`SubjectPublicKeyInfo`) are chosen to define the exact serialization.

Parameters

- **encoding** – A value from the `Encoding` enum.
- **format** – A value from the `PublicFormat` enum.

Return bytes Serialized key.

verify (*signature, data, signature_algorithm*)

New in version 1.5.

Verify one block of data was signed by the private key associated with this public key.

Parameters

- **signature** (*bytes*) – The signature to verify.
- **data** (*bytes*) – The message string that was signed.
- **signature_algorithm** – An instance of `EllipticCurveSignatureAlgorithm`.

Raises `cryptography.exceptions.InvalidSignature` – If the signature does not validate.

key_size

New in version 1.9.

Type `int`

Size (in bits) of a secret scalar for the curve (as generated by `generate_private_key()`).

class `cryptography.hazmat.primitives.asymmetric.ec.EllipticCurvePublicKeyWithSerialization`
 New in version 0.6.

Alias for `EllipticCurvePublicKey`.

Serialization

This sample demonstrates how to generate a private key and serialize it.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.asymmetric import ec
>>> from cryptography.hazmat.primitives import serialization

>>> private_key = ec.generate_private_key(ec.SECP384R1(), default_backend())
```

```
>>> serialized_private = private_key.private_bytes(
...     encoding=serialization.Encoding.PEM,
...     format=serialization.PrivateFormat.PKCS8,
...     encryption_algorithm=serialization.BestAvailableEncryption(b'testpassword')
... )
>>> serialized_private.splitlines()[0]
'-----BEGIN ENCRYPTED PRIVATE KEY-----'
```

You can also serialize the key without a password, by relying on *NoEncryption*.

The public key is serialized as follows:

```
>>> public_key = private_key.public_key()
>>> serialized_public = public_key.public_bytes(
...     encoding=serialization.Encoding.PEM,
...     format=serialization.PublicFormat.SubjectPublicKeyInfo
... )
>>> serialized_public.splitlines()[0]
'-----BEGIN PUBLIC KEY-----'
```

This is the part that you would normally share with the rest of the world.

Key loading

This extends the sample in the previous section, assuming that the variables `serialized_private` and `serialized_public` contain the respective keys in PEM format.

```
>>> loaded_public_key = serialization.load_pem_public_key(
...     serialized_public,
...     backend=default_backend()
... )

>>> loaded_private_key = serialization.load_pem_private_key(
...     serialized_private,
...     # or password=None, if in plain text
...     password=b'testpassword',
...     backend=default_backend()
... )
```

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

RSA

RSA is a public-key algorithm for encrypting and signing messages.

Generation

Unlike symmetric cryptography, where the key is typically just a random series of bytes, RSA keys have a complex internal structure with [specific mathematical properties](#).

`cryptography.hazmat.primitives.asymmetric.rsa.generate_private_key` (*public_exponent*,
key_size,
backend)

New in version 0.5.

Generates a new RSA private key using the provided backend. `key_size` describes how many bits long the key should be, larger keys provide more security, currently 1024 and below are considered breakable, and 2048 or 4096 are reasonable default key sizes for new keys. The `public_exponent` indicates what one mathematical property of the key generation will be. Unless you have a specific reason to do otherwise, you should always use 65537.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives.asymmetric import rsa
>>> private_key = rsa.generate_private_key(
...     public_exponent=65537,
...     key_size=2048,
...     backend=default_backend()
... )
```

Parameters

- **public_exponent** (*int*) – The public exponent of the new key. Usually one of the small Fermat primes 3, 5, 17, 257, 65537. If in doubt you should use 65537.
- **key_size** (*int*) – The length of the modulus in bits. For keys generated in 2015 it is strongly recommended to be at least 2048 (See page 41). It must not be less than 512. Some backends may have additional limitations.
- **backend** – A backend which implements *RSABackend*.

Returns An instance of *RSAPrivateKey*.

Raises *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *RSABackend*

Key loading

If you already have an on-disk key in the PEM format (which are recognizable by the distinctive `-----BEGIN {format}-----` and `-----END {format}-----` markers), you can load it:

```
>>> from cryptography.hazmat.primitives import serialization
>>> with open("path/to/key.pem", "rb") as key_file:
...     private_key = serialization.load_pem_private_key(
...         key_file.read(),
...         password=None,
...         backend=default_backend()
...     )
```

Serialized keys may optionally be encrypted on disk using a password. In this example we loaded an unencrypted key, and therefore we did not provide a password. If the key is encrypted we can pass a `bytes` object as the `password` argument.

There is also support for *loading public keys in the SSH format*.

Key serialization

If you have a private key that you've loaded or generated which implements the *RSAPrivateKeyWithSerialization* interface you can use *private_bytes()* to serialize the key.

```
>>> from cryptography.hazmat.primitives import serialization
>>> pem = private_key.private_bytes(
...     encoding=serialization.Encoding.PEM,
...     format=serialization.PrivateFormat.PKCS8,
...     encryption_algorithm=serialization.BestAvailableEncryption(b'mypassword')
... )
>>> pem.splitlines()[0]
'-----BEGIN ENCRYPTED PRIVATE KEY-----'
```

It is also possible to serialize without encryption using *NoEncryption*.

```
>>> pem = private_key.private_bytes(
...     encoding=serialization.Encoding.PEM,
...     format=serialization.PrivateFormat.TraditionalOpenSSL,
...     encryption_algorithm=serialization.NoEncryption()
... )
>>> pem.splitlines()[0]
'-----BEGIN RSA PRIVATE KEY-----'
```

For public keys you can use *public_bytes()* to serialize the key.

```
>>> from cryptography.hazmat.primitives import serialization
>>> public_key = private_key.public_key()
>>> pem = public_key.public_bytes(
...     encoding=serialization.Encoding.PEM,
...     format=serialization.PublicFormat.SubjectPublicKeyInfo
... )
>>> pem.splitlines()[0]
'-----BEGIN PUBLIC KEY-----'
```

Signing

A private key can be used to sign a message. This allows anyone with the public key to verify that the message was created by someone who possesses the corresponding private key. RSA signatures require a specific hash function, and padding to be used. Here is an example of signing message using RSA, with a secure hash function and padding:

```
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.asymmetric import padding
>>> message = b"A message I want to sign"
>>> signature = private_key.sign(
...     message,
...     padding.PSS(
...         mgf=padding.MGF1(hashes.SHA256()),
...         salt_length=padding.PSS.MAX_LENGTH
...     ),
...     hashes.SHA256()
... )
```

Valid paddings for signatures are *PSS* and *PKCS1v15*. PSS is the recommended choice for any new protocols or applications, PKCS1v15 should only be used to support legacy protocols.

If your data is too large to be passed in a single call, you can hash it separately and pass that value using *Prehashed*.

```
>>> from cryptography.hazmat.primitives.asymmetric import utils
>>> chosen_hash = hashes.SHA256()
>>> hasher = hashes.Hash(chosen_hash, default_backend())
>>> hasher.update(b"data & ")
>>> hasher.update(b"more data")
>>> digest = hasher.finalize()
>>> sig = private_key.sign(
...     digest,
...     padding.PSS(
...         mgf=padding.MGF1(hashes.SHA256()),
...         salt_length=padding.PSS.MAX_LENGTH
...     ),
...     utils.Prehashed(chosen_hash)
... )
```

Verification

The previous section describes what to do if you have a private key and want to sign something. If you have a public key, a message, a signature, and the signing algorithm that was used you can check that the private key associated with a given public key was used to sign that specific message. You can obtain a public key to use in verification using *load_pem_public_key()*, *load_der_public_key()*, *public_key()*, or *public_key()*.

```
>>> public_key = private_key.public_key()
>>> public_key.verify(
...     signature,
...     message,
...     padding.PSS(
...         mgf=padding.MGF1(hashes.SHA256()),
...         salt_length=padding.PSS.MAX_LENGTH
...     ),
...     hashes.SHA256()
... )
```

If the signature does not match, *verify()* will raise an *InvalidSignature* exception.

If your data is too large to be passed in a single call, you can hash it separately and pass that value using *Prehashed*.

```
>>> chosen_hash = hashes.SHA256()
>>> hasher = hashes.Hash(chosen_hash, default_backend())
>>> hasher.update(b"data & ")
>>> hasher.update(b"more data")
>>> digest = hasher.finalize()
>>> public_key.verify(
...     sig,
...     digest,
...     padding.PSS(
...         mgf=padding.MGF1(hashes.SHA256()),
...         salt_length=padding.PSS.MAX_LENGTH
...     ),
...     utils.Prehashed(chosen_hash)
... )
```

Encryption

RSA encryption is interesting because encryption is performed using the **public** key, meaning anyone can encrypt data. The data is then decrypted using the **private** key.

Like signatures, RSA supports encryption with several different padding options. Here's an example using a secure padding and hash function:

```
>>> message = b"encrypted data"
>>> ciphertext = public_key.encrypt(
...     message,
...     padding.OAEP(
...         mgf=padding.MGF1(algorithm=hashes.SHA1()),
...         algorithm=hashes.SHA1(),
...         label=None
...     )
... )
```

Valid paddings for encryption are *OAEP* and *PKCS1v15*. OAEP is the recommended choice for any new protocols or applications, PKCS1v15 should only be used to support legacy protocols.

Decryption

Once you have an encrypted message, it can be decrypted using the private key:

```
>>> plaintext = private_key.decrypt(
...     ciphertext,
...     padding.OAEP(
...         mgf=padding.MGF1(algorithm=hashes.SHA1()),
...         algorithm=hashes.SHA1(),
...         label=None
...     )
... )
>>> plaintext == message
True
```

Padding

class `cryptography.hazmat.primitives.asymmetric.padding.AsymmetricPadding`

New in version 0.2.

name

class `cryptography.hazmat.primitives.asymmetric.padding.PSS(mgf, salt_length)`

New in version 0.3.

Changed in version 0.4: Added `salt_length` parameter.

PSS (Probabilistic Signature Scheme) is a signature scheme defined in [RFC 3447](#). It is more complex than PKCS1 but possesses a [security proof](#). This is the [recommended padding algorithm](#) for RSA signatures. It cannot be used with RSA encryption.

Parameters

- **mgf** – A mask generation function object. At this time the only supported MGF is *MGF1*.

- **salt_length** (*int*) – The length of the salt. It is recommended that this be set to `PSS.MAX_LENGTH`.

MAX_LENGTH

Pass this attribute to `salt_length` to get the maximum salt length available.

class `cryptography.hazmat.primitives.asymmetric.padding.OAEP` (*mgf, algorithm, label*)
New in version 0.4.

OAEP (Optimal Asymmetric Encryption Padding) is a padding scheme defined in [RFC 3447](#). It provides probabilistic encryption and is [proven secure](#) against several attack types. This is the [recommended padding algorithm](#) for RSA encryption. It cannot be used with RSA signing.

Parameters

- **mgf** – A mask generation function object. At this time the only supported MGF is [MGF1](#).
- **algorithm** – An instance of [HashAlgorithm](#).
- **label** (*bytes*) – A label to apply. This is a rarely used field and should typically be set to `None` or `b""`, which are equivalent.

class `cryptography.hazmat.primitives.asymmetric.padding.PKCS1v15`
New in version 0.3.

PKCS1 v1.5 (also known as simply PKCS1) is a simple padding scheme developed for use with RSA keys. It is defined in [RFC 3447](#). This padding can be used for signing and encryption.

It is not recommended that PKCS1v15 be used for new applications, [OAEP](#) should be preferred for encryption and [PSS](#) should be preferred for signatures.

`cryptography.hazmat.primitives.asymmetric.padding.calculate_max_pss_salt_length` (*key, hash_algorithm*)

New in version 1.5.

Parameters

- **key** – An RSA public or private key.
- **hash_algorithm** – A `cryptography.hazmat.primitives.hashes.HashAlgorithm`.

Returns int The computed salt length.

Computes the length of the salt that [PSS](#) will use if `PSS.MAX_LENGTH` is used.

Mask generation functions

class `cryptography.hazmat.primitives.asymmetric.padding.MGF1` (*algorithm*)
New in version 0.3.

Changed in version 0.6: Removed the deprecated `salt_length` parameter.

MGF1 (Mask Generation Function 1) is used as the mask generation function in [PSS](#) and [OAEP](#) padding. It takes a hash algorithm.

Parameters **algorithm** – An instance of [HashAlgorithm](#).

Numbers

These classes hold the constituent components of an RSA key. They are useful only when more traditional [Key Serialization](#) is unavailable.

class `cryptography.hazmat.primitives.asymmetric.rsa.RSAPublicNumbers` (*e*, *n*)
 New in version 0.5.

The collection of integers that make up an RSA public key.

n

Type `int`

The public modulus.

e

Type `int`

The public exponent.

public_key (*backend*)

Parameters *backend* – An instance of `RSABackend`.

Returns A new instance of `RSAPublicKey`.

class `cryptography.hazmat.primitives.asymmetric.rsa.RSAPrivateNumbers` (*p*, *q*, *d*,
dmp1,
dmq1,
iqmp,
public_numbers)
 New in version 0.5.

The collection of integers that make up an RSA private key.

Warning: With the exception of the integers contained in the `RSAPublicNumbers` all attributes of this class must be kept secret. Revealing them will compromise the security of any cryptographic operations performed with a key loaded from them.

public_numbers

Type `RSAPublicNumbers`

The `RSAPublicNumbers` which makes up the RSA public key associated with this RSA private key.

p

Type `int`

p, one of the two primes composing *n*.

q

Type `int`

q, one of the two primes composing *n*.

d

Type `int`

The private exponent.

dmp1

Type `int`

A [Chinese remainder theorem](#) coefficient used to speed up RSA operations. Calculated as: $d \bmod (p-1)$

dmq1**Type** intA Chinese remainder theorem coefficient used to speed up RSA operations. Calculated as: $d \bmod (q-1)$ **iqmp****Type** intA Chinese remainder theorem coefficient used to speed up RSA operations. Calculated as: $q^{-1} \bmod p$ **private_key** (*backend*)**Parameters** **backend** – A new instance of *RSABackend*.**Returns** An instance of *RSAPrivateKey*.

Handling partial RSA private keys

If you are trying to load RSA private keys yourself you may find that not all parameters required by *RSAPrivateNumbers* are available. In particular the Chinese Remainder Theorem (CRT) values *dmq1*, *dmq1*, *iqmp* may be missing or present in a different form. For example, *OpenPGP* does not include the *iqmp*, *dmp1* or *dmq1* parameters.

The following functions are provided for users who want to work with keys like this without having to do the math themselves.

```
cryptography.hazmat.primitives.asymmetric.rsa.rsa_crt_iqmp(p, q)
```

New in version 0.4.

Computes the *iqmp* (also known as *qInv*) parameter from the RSA primes *p* and *q*.

```
cryptography.hazmat.primitives.asymmetric.rsa.rsa_crt_dmp1(private_exponent, p)
```

New in version 0.4.

Computes the *dmp1* parameter from the RSA private exponent (*d*) and prime *p*.

```
cryptography.hazmat.primitives.asymmetric.rsa.rsa_crt_dmq1(private_exponent, q)
```

New in version 0.4.

Computes the *dmq1* parameter from the RSA private exponent (*d*) and prime *q*.

```
cryptography.hazmat.primitives.asymmetric.rsa.rsa_recover_prime_factors(n,
                                                                    e,
                                                                    d)
```

New in version 0.8.

Computes the prime factors (*p*, *q*) given the modulus, public exponent, and private exponent.

Note: When recovering prime factors this algorithm will always return *p* and *q* such that $p > q$. Note: before 1.5, this function always returned *p* and *q* such that $p < q$. It was changed because libraries commonly require $p > q$.

Returns A tuple (*p*, *q*)

Key interfaces

class `cryptography.hazmat.primitives.asymmetric.rsa.RSAPrivateKey`

New in version 0.2.

An RSA private key.

decrypt (*ciphertext*, *padding*)

New in version 0.4.

Decrypt data that was encrypted with the public key.

Parameters

- **ciphertext** (*bytes*) – The ciphertext to decrypt.
- **padding** – An instance of *AsymmetricPadding*.

Return bytes Decrypted data.

public_key ()

Returns *RSAPublicKey*

An RSA public key object corresponding to the values of the private key.

key_size

Type `int`

The bit length of the modulus.

sign (*data*, *padding*, *algorithm*)

New in version 1.4.

Changed in version 1.6: *Prehashed* can now be used as an algorithm.

Sign one block of data which can be verified later by others using the public key.

Parameters

- **data** (*bytes*) – The message string to sign.
- **padding** – An instance of *AsymmetricPadding*.
- **algorithm** – An instance of *HashAlgorithm* or *Prehashed* if the data you want to sign has already been hashed.

Return bytes Signature.

class `cryptography.hazmat.primitives.asymmetric.rsa.RSAPrivateKeyWithSerialization`

New in version 0.8.

Extends *RSAPrivateKey*.

private_numbers ()

Create a *RSAPrivateNumbers* object.

Returns An *RSAPrivateNumbers* instance.

private_bytes (*encoding*, *format*, *encryption_algorithm*)

Allows serialization of the key to bytes. Encoding (*PEM* or *DER*), format (*TraditionalOpenSSL* or *PKCS8*) and encryption algorithm (such as *BestAvailableEncryption* or *NoEncryption*) are chosen to define the exact serialization.

Parameters

- **encoding** – A value from the *Encoding* enum.

- **format** – A value from the *PrivateFormat* enum.
- **encryption_algorithm** – An instance of an object conforming to the *KeySerializationEncryption* interface.

Return bytes Serialized key.

class `cryptography.hazmat.primitives.asymmetric.rsa.RSAPublicKey`

New in version 0.2.

An *RSA* public key.

encrypt (*plaintext, padding*)

New in version 0.4.

Encrypt data with the public key.

Parameters

- **plaintext** (*bytes*) – The plaintext to encrypt.
- **padding** – An instance of *AsymmetricPadding*.

Return bytes Encrypted data.

key_size

Type `int`

The bit length of the modulus.

public_numbers ()

Create a *RSAPublicNumbers* object.

Returns An *RSAPublicNumbers* instance.

public_bytes (*encoding, format*)

Allows serialization of the key to bytes. Encoding (*PEM* or *DER*) and format (*SubjectPublicKeyInfo* or *PKCS1*) are chosen to define the exact serialization.

Parameters

- **encoding** – A value from the *Encoding* enum.
- **format** – A value from the *PublicFormat* enum.

Return bytes Serialized key.

verify (*signature, data, padding, algorithm*)

New in version 1.4.

Changed in version 1.6: *Prehashed* can now be used as an algorithm.

Verify one block of data was signed by the private key associated with this public key.

Parameters

- **signature** (*bytes*) – The signature to verify.
- **data** (*bytes*) – The message string that was signed.
- **padding** – An instance of *AsymmetricPadding*.
- **algorithm** – An instance of *HashAlgorithm* or *Prehashed* if the data you want to sign has already been hashed.

Raises `cryptography.exceptions.InvalidSignature` – If the signature does not validate.

`class cryptography.hazmat.primitives.asymmetric.rsa.RSAPublicKeyWithSerialization`
New in version 0.8.
Alias for `RSAPublicKey`.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Diffie-Hellman key exchange

Note: For security and performance reasons we suggest using `ECDH` instead of `DH` where possible.

Diffie-Hellman key exchange (D–H) is a method that allows two parties to jointly agree on a shared secret using an insecure channel.

Exchange Algorithm

For most applications the `shared_key` should be passed to a key derivation function.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives.asymmetric import dh
>>> # Generate some parameters. These can be reused.
>>> parameters = dh.generate_parameters(generator=2, key_size=2048,
...                                   backend=default_backend())
>>> # Generate a private key for use in the exchange.
>>> private_key = parameters.generate_private_key()
>>> # In a real handshake the peer_public_key will be received from the
>>> # other party. For this example we'll generate another private key and
>>> # get a public key from that. Note that in a DH handshake both peers
>>> # must agree on a common set of parameters.
>>> peer_public_key = parameters.generate_private_key().public_key()
>>> shared_key = private_key.exchange(peer_public_key)
>>> # For the next handshake we MUST generate another private key, but
>>> # we can reuse the parameters.
>>> private_key_2 = parameters.generate_private_key()
>>> peer_public_key_2 = parameters.generate_private_key().public_key()
>>> shared_key_2 = private_key_2.exchange(peer_public_key_2)
```

DHE (or EDH), the ephemeral form of this exchange, is **strongly preferred** over simple `DH` and provides **forward secrecy** when used. You must generate a new private key using `generate_private_key()` for each `exchange()` when performing an DHE key exchange. This is demonstrated in the previous example.

To assemble a `DHParameters` and a `DHPublicKey` from primitive integers, you must first create the `DHParameterNumbers` and `DHPublicNumbers` objects. For example, if `p`, `g`, and `y` are `int` objects received from a peer:

```
pn = dh.DHParameterNumbers(p, g)
parameters = pn.parameters(default_backend())
peer_public_numbers = dh.DHPublicNumbers(y, pn)
peer_public_key = peer_public_numbers.public_key(default_backend())
```

See also the `DHBackend` API for additional functionality.

Group parameters

`cryptography.hazmat.primitives.asymmetric.dh.generate_parameters` (*generator*,
key_size,
backend)

New in version 0.9.

Generate a new DH parameter group for use with `backend`.

Parameters

- **generator** – The `int` to use as a generator. Must be 2 or 5.
- **key_size** – The bit length of the prime modulus to generate.
- **backend** – A `DHBackend` instance.

Returns DH parameters as a new instance of `DHParameters`.

Raises `ValueError` – If `key_size` is not at least 512.

class `cryptography.hazmat.primitives.asymmetric.dh.DHParameters`

New in version 0.9.

generate_private_key ()

New in version 0.9.

Generate a DH private key. This method can be used to generate many new private keys from a single set of parameters.

Returns An instance of `DHPrivateKey`.

class `cryptography.hazmat.primitives.asymmetric.dh.DHParametersWithSerialization`

New in version 0.9.

Inherits from `DHParameters`.

parameter_numbers ()

Return the numbers that make up this set of parameters.

Returns A `DHParameterNumbers`.

Key interfaces

class `cryptography.hazmat.primitives.asymmetric.dh.DHPrivateKey`

New in version 0.9.

key_size

The bit length of the prime modulus.

public_key ()

Return the public key associated with this private key.

Returns A `DHPublicKey`.

parameters ()

Return the parameters associated with this private key.

Returns A `DHParameters`.

exchange (*peer_public_key*)

New in version 1.7.

Parameters `peer_public_key` (`DHPublicKeyWithSerialization`) – The public key for the peer.

Return bytes The agreed key. The bytes are ordered in ‘big’ endian.

class `cryptography.hazmat.primitives.asymmetric.dh.DHPrivateKeyWithSerialization`
New in version 0.9.

Inherits from `DHPrivateKey`.

private_numbers ()

Return the numbers that make up this private key.

Returns A `DHPrivateNumbers`.

private_bytes (`encoding, format, encryption_algorithm`)

New in version 1.8.

Allows serialization of the key to bytes. Encoding (`PEM` or `DER`), format (`PKCS8`) and encryption algorithm (such as `BestAvailableEncryption` or `NoEncryption`) are chosen to define the exact serialization.

Parameters

- **encoding** – A value from the `Encoding` enum.
- **format** – A value from the `PrivateFormat` enum.
- **encryption_algorithm** – An instance of an object conforming to the `KeySerializationEncryption` interface.

Return bytes Serialized key.

class `cryptography.hazmat.primitives.asymmetric.dh.DHPublicKey`
New in version 0.9.

key_size

The bit length of the prime modulus.

parameters ()

Return the parameters associated with this private key.

Returns A `DHParameters`.

class `cryptography.hazmat.primitives.asymmetric.dh.DHPublicKeyWithSerialization`
New in version 0.9.

Inherits from `DHPublicKey`.

public_numbers ()

Return the numbers that make up this public key.

Returns A `DHPublicNumbers`.

public_bytes (`encoding, format`)

New in version 1.8.

Allows serialization of the key to bytes. Encoding (`PEM` or `DER`) and format (`SubjectPublicKeyInfo`) are chosen to define the exact serialization.

Parameters

- **encoding** – A value from the `Encoding` enum.
- **format** – A value from the `PublicFormat` enum.

Return bytes Serialized key.

Numbers

class `cryptography.hazmat.primitives.asymmetric.dh.DHParameterNumbers` (*p*, *g*,
q=None)

New in version 0.8.

The collection of integers that define a Diffie-Hellman group.

p

Type `int`

The prime modulus value.

g

Type `int`

The generator value. Must be 2 or 5 (Unless q is given).

q

New in version 1.8.

Type `int`

p subgroup order value.

class `cryptography.hazmat.primitives.asymmetric.dh.DHPrivateNumbers` (*x*, *public_numbers*)

New in version 0.8.

The collection of integers that make up a Diffie-Hellman private key.

public_numbers

Type `DHPublicNumbers`

The `DHPublicNumbers` which makes up the DH public key associated with this DH private key.

x

Type `int`

The private value.

class `cryptography.hazmat.primitives.asymmetric.dh.DHPublicNumbers` (*y*, *parameter_numbers*)

New in version 0.8.

The collection of integers that make up a Diffie-Hellman public key.

parameter_numbers

Type `DHParameterNumbers`

The parameters for this DH group.

y

Type `int`

The public value.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Key Serialization

There are several common schemes for serializing asymmetric private and public keys to bytes. They generally support encryption of private keys and additional key metadata.

Many serialization formats support multiple different types of asymmetric keys and will return an instance of the appropriate type. You should check that the returned key matches the type your application expects when using these methods.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives.asymmetric import dsa, rsa
>>> from cryptography.hazmat.primitives.serialization import load_pem_
↳private_key
>>> key = load_pem_private_key(pem_data, password=None, backend=default_
↳backend())
>>> if isinstance(key, rsa.RSAPrivateKey):
...     signature = sign_with_rsa_key(key, message)
... elif isinstance(key, dsa.DSAPrivateKey):
...     signature = sign_with_dsa_key(key, message)
... else:
...     raise TypeError
```

Key dumping

The serialization module contains functions for loading keys from bytes. To dump a key object to bytes, you must call the appropriate method on the key object. Documentation for these methods is found in the [rsa](#), [dsa](#), and [ec](#) module documentation.

PEM

PEM is an encapsulation format, meaning keys in it can actually be any of several different key types. However these are all self-identifying, so you don't need to worry about this detail. PEM keys are recognizable because they all begin with -----BEGIN {format}----- and end with -----END {format}-----.

Note: A PEM block which starts with -----BEGIN CERTIFICATE----- is not a public or private key, it's an *X.509 Certificate*. You can load it using `load_pem_x509_certificate()` and extract the public key with `Certificate.public_key`.

`cryptography.hazmat.primitives.serialization.load_pem_private_key`(*data*, *password*, *backend*)

New in version 0.6.

Deserialize a private key from PEM encoded data to one of the supported asymmetric private key types.

Parameters

- **data** (*bytes*) – The PEM encoded key data.
- **password** (*bytes*) – The password to use to decrypt the data. Should be `None` if the private key is not encrypted.
- **backend** – An instance of `PEMSerializationBackend`.

Returns One of `RSAPrivateKey`, `DSAPrivateKey`, `DHPrivateKey`, or `EllipticCurvePrivateKey` depending on the contents of data.

Raises

- **ValueError** – If the PEM data could not be decrypted or if its structure could not be decoded successfully.
- **TypeError** – If a password was given and the private key was not encrypted. Or if the key was encrypted but no password was supplied.
- `cryptography.exceptions.UnsupportedAlgorithm` – If the serialized key is of a type that is not supported by the backend or if the key is encrypted with a symmetric cipher that is not supported by the backend.

```

cryptography.hazmat.primitives.serialization.load_pem_public_key(data, back-
                                                                    end)

```

New in version 0.6.

Deserialize a public key from PEM encoded data to one of the supported asymmetric public key types. The PEM encoded data is typically a `subjectPublicKeyInfo` payload as specified in [RFC 5280](#).

```

>>> from cryptography.hazmat.primitives.serialization import load_pem_public_key
>>> key = load_pem_public_key(public_pem_data, backend=default_backend())
>>> isinstance(key, rsa.RSAPublicKey)
True

```

Parameters

- **data** (*bytes*) – The PEM encoded key data.
- **backend** – An instance of `PEMSerializationBackend`.

Returns One of `RSAPublicKey`, `DSAPublicKey`, `DHPublicKey`, or `EllipticCurvePublicKey` depending on the contents of data.

Raises

- **ValueError** – If the PEM data's structure could not be decoded successfully.
- `cryptography.exceptions.UnsupportedAlgorithm` – If the serialized key is of a type that is not supported by the backend.

DER

DER is an ASN.1 encoding type. There are no encapsulation boundaries and the data is binary. DER keys may be in a variety of formats, but as long as you know whether it is a public or private key the loading functions will handle the rest.

```

cryptography.hazmat.primitives.serialization.load_der_private_key(data, pass-
                                                                    word, back-
                                                                    end)

```

New in version 0.8.

Deserialize a private key from DER encoded data to one of the supported asymmetric private key types.

Parameters

- **data** (*bytes*) – The DER encoded key data.
- **password** (*bytes*) – The password to use to decrypt the data. Should be `None` if the private key is not encrypted.

- **backend** – An instance of *DERSerializationBackend*.

Returns One of *RSAPrivateKey*, *DSAPrivateKey*, *DHPrivateKey*, or *EllipticCurvePrivateKey* depending on the contents of data.

Raises

- **ValueError** – If the DER data could not be decrypted or if its structure could not be decoded successfully.
- **TypeError** – If a password was given and the private key was not encrypted. Or if the key was encrypted but no password was supplied.
- *cryptography.exceptions.UnsupportedAlgorithm* – If the serialized key is of a type that is not supported by the backend or if the key is encrypted with a symmetric cipher that is not supported by the backend.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives.asymmetric import rsa
>>> from cryptography.hazmat.primitives.serialization import load_der_private_key
>>> key = load_der_private_key(der_data, password=None, backend=default_backend())
>>> isinstance(key, rsa.RSAPrivateKey)
True
```

`cryptography.hazmat.primitives.serialization.load_der_public_key(data, backend)`

New in version 0.8.

Deserialize a public key from DER encoded data to one of the supported asymmetric public key types. The DER encoded data is typically a `subjectPublicKeyInfo` payload as specified in [RFC 5280](#).

Parameters

- **data** (*bytes*) – The DER encoded key data.
- **backend** – An instance of *DERSerializationBackend*.

Returns One of *RSAPublicKey*, *DSAPublicKey*, *DHPublicKey*, or *EllipticCurvePublicKey* depending on the contents of data.

Raises

- **ValueError** – If the DER data's structure could not be decoded successfully.
- *cryptography.exceptions.UnsupportedAlgorithm* – If the serialized key is of a type that is not supported by the backend.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives.asymmetric import rsa
>>> from cryptography.hazmat.primitives.serialization import load_der_public_key
>>> key = load_der_public_key(public_der_data, backend=default_backend())
>>> isinstance(key, rsa.RSAPublicKey)
True
```

OpenSSH Public Key

The format used by OpenSSH to store public keys, as specified in [RFC 4253](#).

An example RSA key in OpenSSH format (line breaks added for formatting purposes):

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAQDDu/XRP1kyK6Cgt36gts9XAk
FiiuJLW6RU0j3KKVZSs1I7Z3UmU9/9aVh/rZV43WQG8jaR6kkcP4stOR0DEt1l
PDA7ZRBnrFiHpSQYQ874AZaAoIjgkv7DBfsE6gcDQLub0PFjWyrYQUJhtOLQEK
vY/G0vt2iRL3juawWmCFdTK3W3XvwAdgGk71i61Ht+deOPNEPN2H58E4odrZ2f
sxn/adpDqfb2sM0kPwQs0aWvrrKGvUaustkivQE4XWiSFnB0oJB/1KK/CKVKuy
///ImSCGHQRvhwariN2tvZ6CBNSLh3iQgeB0AkyJlmg7MXB2qYq/Ci2FUOryCX
2MzHvnbv testkey@localhost
```

DSA keys look almost identical but begin with `ssh-dss` rather than `ssh-rsa`. ECDSA keys have a slightly different format, they begin with `ecdsa-sha2-{curve}`.

`cryptography.hazmat.primitives.serialization.load_ssh_public_key` (*data*, *backend*)

New in version 0.7.

Deserialize a public key from OpenSSH ([RFC 4253](#)) encoded data to an instance of the public key type for the specified backend.

Note: Currently Ed25519 keys are not supported.

Parameters

- **data** (*bytes*) – The OpenSSH encoded key data.
- **backend** – A backend which implements *RSABackend*, *DSABackend*, or *EllipticCurveBackend* depending on the key’s type.

Returns One of *RSAPublicKey*, *DSAPublicKey*, or *EllipticCurvePublicKey* depending on the contents of data.

Raises

- **ValueError** – If the OpenSSH data could not be properly decoded or if the key is not in the proper format.
- *cryptography.exceptions.UnsupportedAlgorithm* – If the serialized key is of a type that is not supported.

Serialization Formats

class `cryptography.hazmat.primitives.serialization.PrivateFormat`

New in version 0.8.

An enumeration for private key formats. Used with the `private_bytes` method available on *RSAPrivateKeyWithSerialization*, *EllipticCurvePrivateKeyWithSerialization*, *DHPPrivateKeyWithSerialization* and *DSAPrivateKeyWithSerialization*.

TraditionalOpenSSL

Frequently known as PKCS#1 format. Still a widely used format, but generally considered legacy.

PKCS8

A more modern format for serializing keys which allows for better encryption. Choose this unless you have explicit legacy compatibility requirements.

class `cryptography.hazmat.primitives.serialization.PublicFormat`

New in version 0.8.

An enumeration for public key formats. Used with the `public_bytes` method available on `RSAPublicKeyWithSerialization`, `EllipticCurvePublicKeyWithSerialization`, `DHPublicKeyWithSerialization`, and `DSAPublicKeyWithSerialization`.

SubjectPublicKeyInfo

This is the typical public key format. It consists of an algorithm identifier and the public key as a bit string. Choose this unless you have specific needs.

PKCS1

Just the public key elements (without the algorithm identifier). This format is RSA only, but is used by some older systems.

OpenSSH

New in version 1.4.

The public key format used by OpenSSH (e.g. as found in `~/.ssh/id_rsa.pub` or `~/.ssh/authorized_keys`).

Serialization Encodings

class `cryptography.hazmat.primitives.serialization.Encoding`

An enumeration for encoding types. Used with the `private_bytes` method available on `RSAPrivateKeyWithSerialization`, `EllipticCurvePrivateKeyWithSerialization`, `DHPrivateKeyWithSerialization` and `DSAPrivateKeyWithSerialization` as well as `public_bytes` on `RSAPublicKeyWithSerialization`, `DHPublicKeyWithSerialization` and `EllipticCurvePublicKeyWithSerialization`.

PEM

New in version 0.8.

For PEM format. This is a base64 format with delimiters.

DER

New in version 0.9.

For DER format. This is a binary format.

OpenSSH

New in version 1.4.

The format used by OpenSSH public keys. This is a text format.

Serialization Encryption Types

class `cryptography.hazmat.primitives.serialization.KeySerializationEncryption`

Objects with this interface are usable as encryption types with methods like `private_bytes` available on `RSAPrivateKeyWithSerialization`, `EllipticCurvePrivateKeyWithSerialization`, `DHPrivateKeyWithSerialization` and `DSAPrivateKeyWithSerialization`. All other classes in this section represent the available choices for encryption and have this interface. They are used with `private_bytes`.

class `cryptography.hazmat.primitives.serialization.BestAvailableEncryption` (*password*)

Encrypt using the best available encryption for a given key's backend. This is a curated encryption choice and the algorithm may change over time.

Parameters `password` (*bytes*) – The password to use for encryption.

class `cryptography.hazmat.primitives.serialization.NoEncryption`
 Do not encrypt.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Asymmetric Utilities

`cryptography.hazmat.primitives.asymmetric.utils.decode_dss_signature` (*signature*)

Takes in signatures generated by the DSA/ECDSA signers and returns a tuple (*r*, *s*). These signatures are ASN.1 encoded Dss-Sig-Value sequences (as defined in [RFC 3279](#))

Parameters *signature* (*bytes*) – The signature to decode.

Returns The decoded tuple (*r*, *s*).

Raises `ValueError` – Raised if the signature is malformed.

`cryptography.hazmat.primitives.asymmetric.utils.encode_dss_signature` (*r*, *s*)

Creates an ASN.1 encoded Dss-Sig-Value (as defined in [RFC 3279](#)) from raw *r* and *s* values.

Parameters

- *r* (*int*) – The raw signature value *r*.
- *s* (*int*) – The raw signature value *s*.

Return bytes The encoded signature.

class `cryptography.hazmat.primitives.asymmetric.utils.Prehashed` (*algorithm*)

New in version 1.6.

Prehashed can be passed as the *algorithm* in the RSA `sign()` and `verify()` as well as DSA `sign()` and `verify()` methods.

For elliptic curves it can be passed as the *algorithm* in `ECDSA` and then used with `sign()` and `verify()`

.

Parameters *algorithm* – An instance of `HashAlgorithm`.

```
>>> import hashlib
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.asymmetric import (
...     padding, rsa, utils
... )
>>> private_key = rsa.generate_private_key(
...     public_exponent=65537,
...     key_size=2048,
...     backend=default_backend()
... )
>>> prehashed_msg = hashlib.sha256(b"A message I want to sign").digest()
>>> signature = private_key.sign(
...     prehashed_msg,
...     padding.PSS(
...         mgf=padding.MGF1(hashes.SHA256()),
...         salt_length=padding.PSS.MAX_LENGTH
...     ),
...     utils.Prehashed(hashes.SHA256())
```

```
... )
>>> public_key = private_key.public_key()
>>> public_key.verify(
...     signature,
...     prehashed_msg,
...     padding.PSS(
...         mgf=padding.MGF1(hashes.SHA256()),
...         salt_length=padding.PSS.MAX_LENGTH
...     ),
...     utils.Prehashed(hashes.SHA256())
... )
```

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

X25519 key exchange

X25519 is an elliptic curve [Diffie-Hellman key exchange](#) using [Curve25519](#). It allows two parties to jointly agree on a shared secret using an insecure channel.

Exchange Algorithm

For most applications the `shared_key` should be passed to a key derivation function.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives.asymmetric.x25519 import X25519PrivateKey
>>> # Generate a private key for use in the exchange.
>>> private_key = X25519PrivateKey.generate()
>>> # In a real handshake the peer_public_key will be received from the
>>> # other party. For this example we'll generate another private key and
>>> # get a public key from that. Note that in a DH handshake both peers
>>> # must agree on a common set of parameters.
>>> peer_public_key = X25519PrivateKey.generate().public_key()
>>> shared_key = private_key.exchange(peer_public_key)
>>> # For the next handshake we MUST generate another private key.
>>> private_key_2 = X25519PrivateKey.generate()
>>> peer_public_key_2 = X25519PrivateKey.generate().public_key()
>>> shared_key_2 = private_key_2.exchange(peer_public_key_2)
```

Key interfaces

class `cryptography.hazmat.primitives.asymmetric.x25519.X25519PrivateKey`

New in version 2.0.

classmethod `generate()`

Generate an X25519 private key.

Returns `X25519PrivateKey`

public_key()

Returns `X25519PublicKey`

exchange (*peer_public_key*)

Parameters *peer_public_key* (`X25519PublicKey`) – The public key for the peer.

Returns bytes A shared key.

class `cryptography.hazmat.primitives.asymmetric.x25519.X25519PublicKey`

New in version 2.0.

classmethod `from_public_bytes` (*data*)

Parameters *data* (*bytes*) – 32 byte public key.

Returns `X25519PublicKey`

```
>>> from cryptography.hazmat.primitives.asymmetric import x25519
>>> private_key = x25519.X25519PrivateKey.generate()
>>> public_key = private_key.public_key()
>>> public_bytes = public_key.public_bytes()
>>> loaded_public_key = x25519.X25519PublicKey.from_public_bytes(public_bytes)
```

public_bytes ()

Returns bytes The raw bytes of the public key.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Constant time functions

This module contains functions for operating with secret data in a way that does not leak information about that data through how long it takes to perform the operation. These functions should be used whenever operating on secret data along with data that is user supplied.

An example would be comparing a HMAC signature received from a client to the one generated by the server code for authentication purposes.

For more information about this sort of issue, see [Coda Hale’s blog post](#) about the timing attacks on KeyCzar and Java’s `MessageDigest.isEqual()`.

`cryptography.hazmat.primitives.constant_time.bytes_eq` (*a*, *b*)

Compares *a* and *b* with one another. If *a* and *b* have different lengths, this returns `False` immediately. Otherwise it compares them in a way that takes the same amount of time, regardless of how many characters are the same between the two.

```
>>> from cryptography.hazmat.primitives import constant_time
>>> constant_time.bytes_eq(b"foo", b"foo")
True
>>> constant_time.bytes_eq(b"foo", b"bar")
False
```

Parameters

- **a** (*bytes*) – The left-hand side.
- **b** (*bytes*) – The right-hand side.

Returns bool True if *a* has the same bytes as *b*, otherwise `False`.

Raises `TypeError` – This exception is raised if `a` or `b` is not `bytes`.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Key derivation functions

Key derivation functions derive bytes suitable for cryptographic operations from passwords or other data sources using a pseudo-random function (PRF). Different KDFs are suitable for different tasks such as:

- Cryptographic key derivation

Deriving a key suitable for use as input to an encryption algorithm. Typically this means taking a password and running it through an algorithm such as `PBKDF2HMAC` or `HKDF`. This process is typically known as *key stretching*.

- Password storage

When storing passwords you want to use an algorithm that is computationally intensive. Legitimate users will only need to compute it once (for example, taking the user’s password, running it through the KDF, then comparing it to the stored value), while attackers will need to do it billions of times. Ideal password storage KDFs will be demanding on both computational and memory resources.

`class cryptography.hazmat.primitives.kdf.pbkdf2.PBKDF2HMAC` (*algorithm, length, salt, iterations, backend*)

New in version 0.2.

`PBKDF2` (Password Based Key Derivation Function 2) is typically used for deriving a cryptographic key from a password. It may also be used for key storage, but an alternate key storage KDF such as `Scrypt` is generally considered a better solution.

This class conforms to the `KeyDerivationFunction` interface.

```
>>> import os
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.kdf.pbkdf2 import PBKDF2HMAC
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> # Salts should be randomly generated
>>> salt = os.urandom(16)
>>> # derive
>>> kdf = PBKDF2HMAC(
...     algorithm=hashes.SHA256(),
...     length=32,
...     salt=salt,
...     iterations=100000,
...     backend=backend
... )
>>> key = kdf.derive(b"my great password")
>>> # verify
>>> kdf = PBKDF2HMAC(
...     algorithm=hashes.SHA256(),
...     length=32,
...     salt=salt,
...     iterations=100000,
...     backend=backend
```

```
... )
>>> kdf.verify(b"my great password", key)
```

Parameters

- **algorithm** – An instance of *HashAlgorithm*.
- **length** (*int*) – The desired length of the derived key. Maximum is $(2^{32} - 1) * \text{algorithm.digest_size}$.
- **salt** (*bytes*) – A salt. Secure values¹ are 128-bits (16 bytes) or longer and randomly generated.
- **iterations** (*int*) – The number of iterations to perform of the hash function. This can be used to control the length of time the operation takes. Higher numbers help mitigate brute force attacks against derived keys. See OWASP's [Password Storage Cheat Sheet](#) for more detailed recommendations if you intend to use this for password storage.
- **backend** – An instance of *PBKDF2HMACBackend*.

Raises

- *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *PBKDF2HMACBackend*
- **TypeError** – This exception is raised if salt is not bytes.

derive (*key_material*)

Parameters **key_material** (*bytes*) – The input key material. For PBKDF2 this should be a password.

Return bytes the derived key.

Raises

- *cryptography.exceptions.AlreadyFinalized* – This is raised when *derive()* or *verify()* is called more than once.
- **TypeError** – This exception is raised if key_material is not bytes.

This generates and returns a new key from the supplied password.

verify (*key_material, expected_key*)

Parameters

- **key_material** (*bytes*) – The input key material. This is the same as key_material in *derive()*.
- **expected_key** (*bytes*) – The expected result of deriving a new key, this is the same as the return value of *derive()*.

Raises

- *cryptography.exceptions.InvalidKey* – This is raised when the derived key does not match the expected key.
- *cryptography.exceptions.AlreadyFinalized* – This is raised when *derive()* or *verify()* is called more than once.

¹ See NIST SP 800-132.

This checks whether deriving a new key from the supplied `key_material` generates the same key as the `expected_key`, and raises an exception if they do not match. This can be used for checking whether the password a user provides matches the stored derived key.

class `cryptography.hazmat.primitives.kdf.hkdf.HKDF` (*algorithm, length, salt, info, backend*)
New in version 0.2.

HKDF (HMAC-based Extract-and-Expand Key Derivation Function) is suitable for deriving keys of a fixed size used for other cryptographic operations.

Warning: HKDF should not be used for password storage.

```
>>> import os
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.kdf.hkdf import HKDF
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> salt = os.urandom(16)
>>> info = b"hkdf-example"
>>> hkdf = HKDF(
...     algorithm=hashes.SHA256(),
...     length=32,
...     salt=salt,
...     info=info,
...     backend=backend
... )
>>> key = hkdf.derive(b"input key")
>>> hkdf = HKDF(
...     algorithm=hashes.SHA256(),
...     length=32,
...     salt=salt,
...     info=info,
...     backend=backend
... )
>>> hkdf.verify(b"input key", key)
```

Parameters

- **algorithm** – An instance of *HashAlgorithm*.
- **length** (*int*) – The desired length of the derived key. Maximum is $255 * (\text{algorithm.digest_size} // 8)$.
- **salt** (*bytes*) – A salt. Randomizes the KDF's output. Optional, but highly recommended. Ideally as many bits of entropy as the security level of the hash: often that means cryptographically random and as long as the hash output. Worse (shorter, less entropy) salt values can still meaningfully contribute to security. May be reused. Does not have to be secret, but may cause stronger security guarantees if secret; see [RFC 5869](#) and the [HKDF paper](#) for more details. If `None` is explicitly passed a default salt of `algorithm.digest_size // 8` null bytes will be used.
- **info** (*bytes*) – Application specific context information. If `None` is explicitly passed an empty byte string will be used.
- **backend** – An instance of *HMACBackend*.

Raises

- `cryptography.exceptions.UnsupportedAlgorithm` – This is raised if the provided backend does not implement `HMACBackend`
- `TypeError` – This exception is raised if `salt` or `info` is not bytes.

derive (*key_material*)

Parameters `key_material` (*bytes*) – The input key material.

Return bytes The derived key.

Raises `TypeError` – This exception is raised if `key_material` is not bytes.

Derives a new key from the input key material by performing both the extract and expand operations.

verify (*key_material, expected_key*)

Parameters

- `key_material` (*bytes*) – The input key material. This is the same as `key_material` in `derive()`.
- `expected_key` (*bytes*) – The expected result of deriving a new key, this is the same as the return value of `derive()`.

Raises

- `cryptography.exceptions.InvalidKey` – This is raised when the derived key does not match the expected key.
- `cryptography.exceptions.AlreadyFinalized` – This is raised when `derive()` or `verify()` is called more than once.

This checks whether deriving a new key from the supplied `key_material` generates the same key as the `expected_key`, and raises an exception if they do not match.

class `cryptography.hazmat.primitives.kdf.hkdf.HKDFExpand` (*algorithm, length, info, backend*)

New in version 0.5.

HKDF consists of two stages, extract and expand. This class exposes an expand only version of HKDF that is suitable when the key material is already cryptographically strong.

Warning: `HKDFExpand` should only be used if the key material is cryptographically strong. You should use `HKDF` if you are unsure.

```
>>> import os
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.kdf.hkdf import HKDFExpand
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> info = b"hkdf-example"
>>> key_material = os.urandom(16)
>>> hkdf = HKDFExpand(
...     algorithm=hashes.SHA256(),
...     length=32,
...     info=info,
...     backend=backend
... )
>>> key = hkdf.derive(key_material)
>>> hkdf = HKDFExpand(
```

```
...     algorithm=hashes.SHA256(),
...     length=32,
...     info=info,
...     backend=backend
... )
>>> hkdf.verify(key_material, key)
```

Parameters

- **algorithm** – An instance of *HashAlgorithm*.
- **length** (*int*) – The desired length of the derived key. Maximum is $255 * (\text{algorithm.digest_size} // 8)$.
- **info** (*bytes*) – Application specific context information. If *None* is explicitly passed an empty byte string will be used.
- **backend** – An instance of *HMACBackend*.

Raises

- *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *HMACBackend*
- **TypeError** – This is raised if the provided *info* is a unicode object
- **TypeError** – This exception is raised if *info* is not *bytes*.

derive (*key_material*)

Parameters **key_material** (*bytes*) – The input key material.

Return bytes The derived key.

Raises

- **TypeError** – This is raised if the provided *key_material* is a unicode object
- **TypeError** – This exception is raised if *key_material* is not *bytes*.

Derives a new key from the input key material by performing both the extract and expand operations.

verify (*key_material*, *expected_key*)

Parameters

- **key_material** (*bytes*) – The input key material. This is the same as *key_material* in *derive()*.
- **expected_key** (*bytes*) – The expected result of deriving a new key, this is the same as the return value of *derive()*.

Raises

- *cryptography.exceptions.InvalidKey* – This is raised when the derived key does not match the expected key.
- *cryptography.exceptions.AlreadyFinalized* – This is raised when *derive()* or *verify()* is called more than once.
- **TypeError** – This is raised if the provided *key_material* is a unicode object

This checks whether deriving a new key from the supplied *key_material* generates the same key as the *expected_key*, and raises an exception if they do not match.

```
class cryptography.hazmat.primitives.kdf.concatkdf.ConcatKDFHash(algorithm,
                                                                length, other-
                                                                info, backend)
```

New in version 1.0.

ConcatKDFHash (Concatenation Key Derivation Function) is defined by the NIST Special Publication NIST SP 800-56Ar2 document, to be used to derive keys for use after a Key Exchange negotiation operation.

Warning: ConcatKDFHash should not be used for password storage.

```
>>> import os
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.kdf.concatkdf import ConcatKDFHash
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> otherinfo = b"concatkdf-example"
>>> ckdf = ConcatKDFHash(
...     algorithm=hashes.SHA256(),
...     length=256,
...     otherinfo=otherinfo,
...     backend=backend
... )
>>> key = ckdf.derive(b"input key")
>>> ckdf = ConcatKDFHash(
...     algorithm=hashes.SHA256(),
...     length=256,
...     otherinfo=otherinfo,
...     backend=backend
... )
>>> ckdf.verify(b"input key", key)
```

Parameters

- **algorithm** – An instance of *HashAlgorithm*.
- **length** (*int*) – The desired length of the derived key in bytes. Maximum is $\text{hashlen} * (2^{32} - 1)$.
- **otherinfo** (*bytes*) – Application specific context information. If None is explicitly passed an empty byte string will be used.
- **backend** – An instance of *HashBackend*.

Raises

- *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *HashBackend*
- **TypeError** – This exception is raised if *otherinfo* is not bytes.

derive (*key_material*)

Parameters *key_material* (*bytes*) – The input key material.

Return bytes The derived key.

Raises **TypeError** – This exception is raised if *key_material* is not bytes.

Derives a new key from the input key material.

verify (*key_material*, *expected_key*)

Parameters

- **key_material** (*bytes*) – The input key material. This is the same as *key_material* in *derive()*.
- **expected_key** (*bytes*) – The expected result of deriving a new key, this is the same as the return value of *derive()*.

Raises

- ***cryptography.exceptions.InvalidKey*** – This is raised when the derived key does not match the expected key.
- ***cryptography.exceptions.AlreadyFinalized*** – This is raised when *derive()* or *verify()* is called more than once.

This checks whether deriving a new key from the supplied *key_material* generates the same key as the *expected_key*, and raises an exception if they do not match.

class `cryptography.hazmat.primitives.kdf.concatkdf.ConcatKDFHMAC` (*algorithm*,
length, *salt*, *otherinfo*, *backend*)

New in version 1.0.

Similar to `ConcatKDFHash` but uses an HMAC function instead.

Warning: `ConcatKDFHMAC` should not be used for password storage.

```
>>> import os
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.kdf.concatkdf import ConcatKDFHMAC
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> salt = os.urandom(16)
>>> otherinfo = b"concatkdf-example"
>>> ckdf = ConcatKDFHMAC(
...     algorithm=hashes.SHA256(),
...     length=256,
...     salt=salt,
...     otherinfo=otherinfo,
...     backend=backend
... )
>>> key = ckdf.derive(b"input key")
>>> ckdf = ConcatKDFHMAC(
...     algorithm=hashes.SHA256(),
...     length=256,
...     salt=salt,
...     otherinfo=otherinfo,
...     backend=backend
... )
>>> ckdf.verify(b"input key", key)
```

Parameters

- **algorithm** – An instance of *HashAlgorithm*.

- **length** (*int*) – The desired length of the derived key in bytes. Maximum is `hashlen * (232 - 1)`.
- **salt** (*bytes*) – A salt. Randomizes the KDF's output. Optional, but highly recommended. Ideally as many bits of entropy as the security level of the hash: often that means cryptographically random and as long as the hash output. Does not have to be secret, but may cause stronger security guarantees if secret; If `None` is explicitly passed a default salt of `algorithm.block_size` null bytes will be used.
- **otherinfo** (*bytes*) – Application specific context information. If `None` is explicitly passed an empty byte string will be used.
- **backend** – An instance of `HMACBackend`.

Raises

- `cryptography.exceptions.UnsupportedAlgorithm` – This is raised if the provided backend does not implement `HMACBackend`
- `TypeError` – This exception is raised if `salt` or `otherinfo` is not `bytes`.

derive (*key_material*)

Parameters `key_material` (*bytes*) – The input key material.

Return bytes The derived key.

Raises `TypeError` – This exception is raised if `key_material` is not `bytes`.

Derives a new key from the input key material.

verify (*key_material, expected_key*)

Parameters

- **key_material** (*bytes*) – The input key material. This is the same as `key_material` in `derive()`.
- **expected_key** (*bytes*) – The expected result of deriving a new key, this is the same as the return value of `derive()`.

Raises

- `cryptography.exceptions.InvalidKey` – This is raised when the derived key does not match the expected key.
- `cryptography.exceptions.AlreadyFinalized` – This is raised when `derive()` or `verify()` is called more than once.

This checks whether deriving a new key from the supplied `key_material` generates the same key as the `expected_key`, and raises an exception if they do not match.

class `cryptography.hazmat.primitives.kdf.x963kdf.X963KDF` (*algorithm, length, otherinfo, backend*)

New in version 1.1.

X963KDF (ANSI X9.63 Key Derivation Function) is defined by ANSI in the [ANSI X9.63:2001](#) document, to be used to derive keys for use after a Key Exchange negotiation operation.

SECG in [SEC 1 v2.0](#) recommends that `ConcatKDFHash` be used for new projects. This KDF should only be used for backwards compatibility with pre-existing protocols.

Warning: X963KDF should not be used for password storage.

```
>>> import os
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.kdf.x963kdf import X963KDF
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> sharedinfo = b"ANSI X9.63 Example"
>>> xkdf = X963KDF(
...     algorithm=hashes.SHA256(),
...     length=256,
...     sharedinfo=sharedinfo,
...     backend=backend
... )
>>> key = xkdf.derive(b"input key")
>>> xkdf = X963KDF(
...     algorithm=hashes.SHA256(),
...     length=256,
...     sharedinfo=sharedinfo,
...     backend=backend
... )
>>> xkdf.verify(b"input key", key)
```

Parameters

- **algorithm** – An instance of *HashAlgorithm*.
- **length** (*int*) – The desired length of the derived key in bytes. Maximum is $\text{hashlen} * (2^{32} - 1)$.
- **sharedinfo** (*bytes*) – Application specific context information. If None is explicitly passed an empty byte string will be used.
- **backend** – A cryptography backend *HashBackend* instance.

Raises

- *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *HashBackend*
- **TypeError** – This exception is raised if *sharedinfo* is not bytes.

derive (*key_material*)

Parameters *key_material* (*bytes*) – The input key material.

Return bytes The derived key.

Raises **TypeError** – This exception is raised if *key_material* is not bytes.

Derives a new key from the input key material.

verify (*key_material*, *expected_key*)

Parameters

- **key_material** (*bytes*) – The input key material. This is the same as *key_material* in *derive* ().
- **expected_key** (*bytes*) – The expected result of deriving a new key, this is the same as the return value of *derive* ().

Raises

- `cryptography.exceptions.InvalidKey` – This is raised when the derived key does not match the expected key.
- `cryptography.exceptions.AlreadyFinalized` – This is raised when `derive()` or `verify()` is called more than once.

This checks whether deriving a new key from the supplied `key_material` generates the same key as the `expected_key`, and raises an exception if they do not match.

class `cryptography.hazmat.primitives.kdf.kbkdf.KBKDFHMAC` (*algorithm, mode, length, rlen, llen, location, label, context, fixed, backend*)

New in version 1.4.

KBKDF (Key Based Key Derivation Function) is defined by the [NIST SP 800-108](#) document, to be used to derive additional keys from a key that has been established through an automated key-establishment scheme.

Warning: KBKDFHMAC should not be used for password storage.

```
>>> import os
>>> from cryptography.hazmat.primitives import hashes
>>> from cryptography.hazmat.primitives.kdf.kbkdf import (
...     CounterLocation, KBKDFHMAC, Mode
... )
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> label = b"KBKDF HMAC Label"
>>> context = b"KBKDF HMAC Context"
>>> kdf = KBKDFHMAC(
...     algorithm=hashes.SHA256(),
...     mode=Mode.CounterMode,
...     length=256,
...     rlen=4,
...     llen=4,
...     location=CounterLocation.BeforeFixed,
...     label=label,
...     context=context,
...     fixed=None,
...     backend=backend
... )
>>> key = kdf.derive(b"input key")
>>> kdf = KBKDFHMAC(
...     algorithm=hashes.SHA256(),
...     mode=Mode.CounterMode,
...     length=256,
...     rlen=4,
...     llen=4,
...     location=CounterLocation.BeforeFixed,
...     label=label,
...     context=context,
...     fixed=None,
...     backend=backend
... )
>>> kdf.verify(b"input key", key)
```

Parameters

- **algorithm** – An instance of *HashAlgorithm*.
- **mode** – The desired mode of the PRF. A value from the *Mode* enum.
- **length** (*int*) – The desired length of the derived key in bytes.
- **rlen** (*int*) – An integer that indicates the length of the binary representation of the counter in bytes.
- **llen** (*int*) – An integer that indicates the binary representation of the length in bytes.
- **location** – The desired location of the counter. A value from the *CounterLocation* enum.
- **label** (*bytes*) – Application specific label information. If *None* is explicitly passed an empty byte string will be used.
- **context** (*bytes*) – Application specific context information. If *None* is explicitly passed an empty byte string will be used.
- **fixed** (*bytes*) – Instead of specifying *label* and *context* you may supply your own fixed data. If *fixed* is specified, *label* and *context* is ignored.
- **backend** – A cryptography backend *HashBackend* instance.

Raises

- *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *HashBackend*
- **TypeError** – This exception is raised if *label* or *context* is not *bytes*. Also raised if *rlen* or *llen* is not *int*.
- **ValueError** – This exception is raised if *rlen* or *llen* is greater than 4 or less than 1. This exception is also raised if you specify a *label* or *context* and *fixed*.

derive (*key_material*)**Parameters** **key_material** (*bytes*) – The input key material.**Return bytes** The derived key.**Raises** **TypeError** – This exception is raised if *key_material* is not *bytes*.

Derives a new key from the input key material.

verify (*key_material*, *expected_key*)**Parameters**

- **key_material** (*bytes*) – The input key material. This is the same as *key_material* in *derive()*.
- **expected_key** (*bytes*) – The expected result of deriving a new key, this is the same as the return value of *derive()*.

Raises

- *cryptography.exceptions.InvalidKey* – This is raised when the derived key does not match the expected key.
- *cryptography.exceptions.AlreadyFinalized* – This is raised when *derive()* or *verify()* is called more than once.

This checks whether deriving a new key from the supplied `key_material` generates the same key as the `expected_key`, and raises an exception if they do not match.

class `cryptography.hazmat.primitives.kdf.kbkdf.Mode`

An enumeration for the key based key derivative modes.

CounterMode

The output of the PRF is computed with a counter as the iteration variable.

class `cryptography.hazmat.primitives.kdf.kbkdf.CounterLocation`

An enumeration for the key based key derivative counter location.

BeforeFixed

The counter iteration variable will be concatenated before the fixed input data.

AfterFixed

The counter iteration variable will be concatenated after the fixed input data.

class `cryptography.hazmat.primitives.kdf.scrypt.Scrypt` (*salt, length, n, r, p, backend*)

New in version 1.6.

Scrypt is a KDF designed for password storage by Colin Percival to be resistant against hardware-assisted attackers by having a tunable memory cost. It is described in [RFC 7914](#).

This class conforms to the `KeyDerivationFunction` interface.

```
>>> import os
>>> from cryptography.hazmat.primitives.kdf.scrypt import Scrypt
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> salt = os.urandom(16)
>>> # derive
>>> kdf = Scrypt(
...     salt=salt,
...     length=64,
...     n=2**14,
...     r=8,
...     p=1,
...     backend=backend
... )
>>> key = kdf.derive(b"my great password")
>>> # verify
>>> kdf = Scrypt(
...     salt=salt,
...     length=64,
...     n=2**14,
...     r=8,
...     p=1,
...     backend=backend
... )
>>> kdf.verify(b"my great password", key)
```

Parameters

- **salt** (*bytes*) – A salt.
- **length** (*int*) – The desired length of the derived key.
- **n** (*int*) – CPU/Memory cost parameter. It must be larger than 1 and be a power of 2.
- **r** (*int*) – Block size parameter.

- `p` (*int*) – Parallelization parameter.

The computational and memory cost of Scrypt can be adjusted by manipulating the 3 parameters: `n`, `r`, and `p`. In general, the memory cost of Scrypt is affected by the values of both `n` and `r`, while `n` also determines the number of iterations performed. `p` increases the computational cost without affecting memory usage. A more in-depth explanation of the 3 parameters can be found [here](#).

[RFC 7914](#) recommends values of `r=8` and `p=1` while scaling `n` to a number appropriate for your system. The [scrypt paper](#) suggests a minimum value of `n=2**14` for interactive logins (`t < 100ms`), or `n=2**20` for more sensitive files (`t < 5s`).

Parameters `backend` – An instance of `ScryptBackend`.

Raises

- `cryptography.exceptions.UnsupportedAlgorithm` – This is raised if the provided `backend` does not implement `ScryptBackend`
- `TypeError` – This exception is raised if `salt` is not `bytes`.
- `ValueError` – This exception is raised if `n` is less than 2, if `n` is not a power of 2, if `r` is less than 1 or if `p` is less than 1.

derive (*key_material*)

Parameters `key_material` (*bytes*) – The input key material.

Return `bytes` the derived key.

Raises

- `TypeError` – This exception is raised if `key_material` is not `bytes`.
- `cryptography.exceptions.AlreadyFinalized` – This is raised when `derive()` or `verify()` is called more than once.

This generates and returns a new key from the supplied password.

verify (*key_material, expected_key*)

Parameters

- `key_material` (*bytes*) – The input key material. This is the same as `key_material` in `derive()`.
- `expected_key` (*bytes*) – The expected result of deriving a new key, this is the same as the return value of `derive()`.

Raises

- `cryptography.exceptions.InvalidKey` – This is raised when the derived key does not match the expected key.
- `cryptography.exceptions.AlreadyFinalized` – This is raised when `derive()` or `verify()` is called more than once.

This checks whether deriving a new key from the supplied `key_material` generates the same key as the `expected_key`, and raises an exception if they do not match. This can be used for checking whether the password a user provides matches the stored derived key.

Interface

class `cryptography.hazmat.primitives.kdf.KeyDerivationFunction`

New in version 0.2.

derive (*key_material*)

Parameters **key_material** (*bytes*) – The input key material. Depending on what key derivation function you are using this could be either random bytes, or a user supplied password.

Returns The new key.

Raises `cryptography.exceptions.AlreadyFinalized` – This is raised when `derive()` or `verify()` is called more than once.

This generates and returns a new key from the supplied key material.

verify (*key_material*, *expected_key*)

Parameters

- **key_material** (*bytes*) – The input key material. This is the same as `key_material` in `derive()`.
- **expected_key** (*bytes*) – The expected result of deriving a new key, this is the same as the return value of `derive()`.

Raises

- `cryptography.exceptions.InvalidKey` – This is raised when the derived key does not match the expected key.
- `cryptography.exceptions.AlreadyFinalized` – This is raised when `derive()` or `verify()` is called more than once.

This checks whether deriving a new key from the supplied `key_material` generates the same key as the `expected_key`, and raises an exception if they do not match. This can be used for something like checking whether a user’s password attempt matches the stored derived key.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Key wrapping

Key wrapping is a cryptographic construct that uses symmetric encryption to encapsulate key material. Key wrapping algorithms are occasionally utilized to protect keys at rest or transmit them over insecure networks. Many of the protections offered by key wrapping are also offered by using authenticated *symmetric encryption*.

```
cryptography.hazmat.primitives.keywrap.aes_key_wrap(wrapping_key, key_to_wrap, backend)
```

New in version 1.1.

This function performs AES key wrap (without padding) as specified in [RFC 3394](#).

Parameters

- **wrapping_key** (*bytes*) – The wrapping key.
- **key_to_wrap** (*bytes*) – The key to wrap.
- **backend** – A `CipherBackend` instance that supports *AES*.

Return bytes The wrapped key as bytes.

`cryptography.hazmat.primitives.keywrap.aes_key_unwrap` (*wrapping_key*, *wrapped_key*, *backend*)

New in version 1.1.

This function performs AES key unwrap (without padding) as specified in [RFC 3394](#).

Parameters

- **wrapping_key** (*bytes*) – The wrapping key.
- **wrapped_key** (*bytes*) – The wrapped key.
- **backend** – A *CipherBackend* instance that supports *AES*.

Return bytes The unwrapped key as bytes.

Raises `cryptography.hazmat.primitives.keywrap.InvalidUnwrap` – This is raised if the key is not successfully unwrapped.

Exceptions

class `cryptography.hazmat.primitives.keywrap.InvalidUnwrap`

This is raised when a wrapped key fails to unwrap. It can be caused by a corrupted or invalid wrapped key or an invalid wrapping key.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Message authentication codes

While cryptography supports both the CMAC and HMAC algorithms, we strongly recommend that HMAC should be used unless you have a good reason otherwise.

For more information on why HMAC is preferred, see [Use cases for CMAC vs. HMAC?](#)

HMAC and CMAC both use the `MACContext` interface:

class `cryptography.hazmat.primitives.mac.MACContext`

New in version 0.7.

update (*data*)

Parameters **data** (*bytes*) – The data you want to authenticate.

finalize ()

Returns The message authentication code.

copy ()

Returns A *MACContext* that is a copy of the current context.

verify (*signature*)

Parameters **signature** (*bytes*) – The signature to verify.

Raises `cryptography.exceptions.InvalidSignature` – This is raised when the provided signature does not match the expected signature.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Cipher-based message authentication code (CMAC)

Cipher-based message authentication codes (or CMACs) are a tool for calculating message authentication codes using a block cipher coupled with a secret key. You can use an CMAC to verify both the integrity and authenticity of a message.

A subset of CMAC with the AES-128 algorithm is described in [RFC 4493](#).

class `cryptography.hazmat.primitives.cmac.CMAC` (*algorithm*, *backend*)
 New in version 0.4.

CMAC objects take a *BlockCipherAlgorithm* instance.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import cmac
>>> from cryptography.hazmat.primitives.ciphers import algorithms
>>> c = cmac.CMAC(algorithms.AES(key), backend=default_backend())
>>> c.update(b"message to authenticate")
>>> c.finalize()
'CT\x1d\xc8\xe0\x15\xe4\xdb\xb6\x84\xca\xd9Xk'
```

If the backend doesn’t support the requested algorithm an *UnsupportedAlgorithm* exception will be raised.

If algorithm isn’t a *BlockCipherAlgorithm* instance then `TypeError` will be raised.

To check that a given signature is correct use the `verify()` method. You will receive an exception if the signature is wrong:

```
>>> c = cmac.CMAC(algorithms.AES(key), backend=default_backend())
>>> c.update(b"message to authenticate")
>>> c.verify(b"an incorrect signature")
Traceback (most recent call last):
...
cryptography.exceptions.InvalidSignature: Signature did not match digest.
```

Parameters

- **algorithm** – An instance of *BlockCipherAlgorithm*.
- **backend** – An instance of *CMACBackend*.

Raises

- **TypeError** – This is raised if the provided algorithm is not an instance of *BlockCipherAlgorithm*
- **`cryptography.exceptions.UnsupportedAlgorithm`** – This is raised if the provided backend does not implement *CMACBackend*

update (*data*)

Parameters **data** (*bytes*) – The bytes to hash and authenticate.

Raises

- `cryptography.exceptions.AlreadyFinalized` – See `finalize()`
- `TypeError` – This exception is raised if data is not bytes.

copy()

Copy this *CMAC* instance, usually so that we may call `finalize()` to get an intermediate value while we continue to call `update()` on the original instance.

Returns A new instance of *CMAC* that can be updated and finalized independently of the original instance.

Raises `cryptography.exceptions.AlreadyFinalized` – See `finalize()`

verify(signature)

Finalize the current context and securely compare the MAC to signature.

Parameters `signature` (*bytes*) – The bytes to compare the current CMAC against.

Raises

- `cryptography.exceptions.AlreadyFinalized` – See `finalize()`
- `cryptography.exceptions.InvalidSignature` – If signature does not match digest
- `TypeError` – This exception is raised if `signature` is not bytes.

finalize()

Finalize the current context and return the message authentication code as bytes.

After `finalize` has been called this object can no longer be used and `update()`, `copy()`, `verify()` and `finalize()` will raise an `AlreadyFinalized` exception.

Return bytes The message authentication code as bytes.

Raises `cryptography.exceptions.AlreadyFinalized` –

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Hash-based message authentication codes (HMAC)

Hash-based message authentication codes (or HMACs) are a tool for calculating message authentication codes using a cryptographic hash function coupled with a secret key. You can use an HMAC to verify both the integrity and authenticity of a message.

class `cryptography.hazmat.primitives.hmac.HMAC` (*key, algorithm, backend*)

HMAC objects take a *key* and a *HashAlgorithm* instance. The *key* should be *randomly generated bytes* and is recommended to be equal in length to the `digest_size` of the hash function chosen. You must keep the *key* secret.

This is an implementation of **RFC 2104**.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes, hmac
>>> h = hmac.HMAC(key, hashes.SHA256(), backend=default_backend())
>>> h.update(b"message to hash")
>>> h.finalize()
'#F\xdaI\x8b"e\xc4\xf1\xbb\x9a\x8fc\xff\xf5\xdex.\xbc\xcd/+\x8a\x86\x1d\x84\
↪ \xc3\xa6\x1d\xd8J'
```

If the backend doesn't support the requested algorithm an *UnsupportedAlgorithm* exception will be raised.

If algorithm isn't a *HashAlgorithm* instance then `TypeError` will be raised.

To check that a given signature is correct use the *verify()* method. You will receive an exception if the signature is wrong:

```
>>> h = hmac.HMAC(key, hashes.SHA256(), backend=default_backend())
>>> h.update(b"message to hash")
>>> h.verify(b"an incorrect signature")
Traceback (most recent call last):
...
cryptography.exceptions.InvalidSignature: Signature did not match digest.
```

Parameters

- **key** (*bytes*) – Secret key as bytes.
- **algorithm** – An *HashAlgorithm* instance such as those described in *Cryptographic Hashes*.
- **backend** – An *HMACBackend* instance.

Raises *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *HMACBackend*

update (*msg*)

Parameters **msg** (*bytes*) – The bytes to hash and authenticate.

Raises

- *cryptography.exceptions.AlreadyFinalized* – See *finalize()*
- `TypeError` – This exception is raised if *msg* is not bytes.

copy ()

Copy this *HMAC* instance, usually so that we may call *finalize()* to get an intermediate digest value while we continue to call *update()* on the original instance.

Returns A new instance of *HMAC* that can be updated and finalized independently of the original instance.

Raises *cryptography.exceptions.AlreadyFinalized* – See *finalize()*

verify (*signature*)

Finalize the current context and securely compare digest to signature.

Parameters **signature** (*bytes*) – The bytes to compare the current digest against.

Raises

- *cryptography.exceptions.AlreadyFinalized* – See *finalize()*
- *cryptography.exceptions.InvalidSignature* – If signature does not match digest
- `TypeError` – This exception is raised if *signature* is not bytes.

finalize ()

Finalize the current context and return the message digest as bytes.

After `finalize` has been called this object can no longer be used and `update()`, `copy()`, `verify()` and `finalize()` will raise an `AlreadyFinalized` exception.

Return bytes The message digest as bytes.

Raises `cryptography.exceptions.AlreadyFinalized` –

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Message digests (Hashing)

class `cryptography.hazmat.primitives.hashes.Hash` (*algorithm, backend*)

A cryptographic hash function takes an arbitrary block of data and calculates a fixed-size bit string (a digest), such that different data results (with a high probability) in different digests.

This is an implementation of `HashContext` meant to be used with `HashAlgorithm` implementations to provide an incremental interface to calculating various message digests.

```
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives import hashes
>>> digest = hashes.Hash(hashes.SHA256(), backend=default_backend())
>>> digest.update(b"abc")
>>> digest.update(b"123")
>>> digest.finalize()
'1\xa1=R\xcap\xc8\x83\xe0\xf0\xbb\x10\x1eBZ\x89\xe8bM\xe5\x1d\xb2\xd29
↪%\x93\xafj\x84\x11\x80\x90'
```

If the backend doesn’t support the requested `algorithm` an `UnsupportedAlgorithm` exception will be raised.

Keep in mind that attacks against cryptographic hashes only get stronger with time, and that often algorithms that were once thought to be strong, become broken. Because of this it’s important to include a plan for upgrading the hash algorithm you use over time. For more information, see [Lifetimes of cryptographic hash functions](#).

Parameters

- **algorithm** – A `HashAlgorithm` instance such as those described in *below*.
- **backend** – A `HashBackend` instance.

Raises `cryptography.exceptions.UnsupportedAlgorithm` – This is raised if the provided `backend` does not implement `HashBackend`

update (*data*)

Parameters `data` (*bytes*) – The bytes to be hashed.

Raises

- `cryptography.exceptions.AlreadyFinalized` – See `finalize()`.
- `TypeError` – This exception is raised if `data` is not bytes.

copy ()

Copy this `Hash` instance, usually so that you may call `finalize()` to get an intermediate digest value while we continue to call `update()` on the original instance.

Returns A new instance of *Hash* that can be updated and finalized independently of the original instance.

Raises `cryptography.exceptions.AlreadyFinalized` – See `finalize()`.

finalize()

Finalize the current context and return the message digest as bytes.

After `finalize` has been called this object can no longer be used and `update()`, `copy()`, and `finalize()` will raise an `AlreadyFinalized` exception.

Return bytes The message digest as bytes.

SHA-2 family

class `cryptography.hazmat.primitives.hashes.SHA224`

SHA-224 is a cryptographic hash function from the SHA-2 family and is standardized by NIST. It produces a 224-bit message digest.

class `cryptography.hazmat.primitives.hashes.SHA256`

SHA-256 is a cryptographic hash function from the SHA-2 family and is standardized by NIST. It produces a 256-bit message digest.

class `cryptography.hazmat.primitives.hashes.SHA384`

SHA-384 is a cryptographic hash function from the SHA-2 family and is standardized by NIST. It produces a 384-bit message digest.

class `cryptography.hazmat.primitives.hashes.SHA512`

SHA-512 is a cryptographic hash function from the SHA-2 family and is standardized by NIST. It produces a 512-bit message digest.

BLAKE2

BLAKE2 is a cryptographic hash function specified in [RFC 7693](#). BLAKE2's design makes it immune to [length-extension attacks](#), an advantage over the SHA-family of hashes.

Note: While the RFC specifies keying, personalization, and salting features, these are not supported at this time due to limitations in OpenSSL 1.1.0.

class `cryptography.hazmat.primitives.hashes.BLAKE2b(digest_size)`

BLAKE2b is optimized for 64-bit platforms and produces an 1 to 64-byte message digest.

Parameters `digest_size` (*int*) – The desired size of the hash output in bytes. Only 64 is supported at this time.

Raises `ValueError` – If the `digest_size` is invalid.

class `cryptography.hazmat.primitives.hashes.BLAKE2s(digest_size)`

BLAKE2s is optimized for 8 to 32-bit platforms and produces a 1 to 32-byte message digest.

Parameters `digest_size` (*int*) – The desired size of the hash output in bytes. Only 32 is supported at this time.

Raises `ValueError` – If the `digest_size` is invalid.

SHA-1

Warning: SHA-1 is a deprecated hash algorithm that has practical known collision attacks. You are strongly discouraged from using it. Existing applications should strongly consider moving away.

class `cryptography.hazmat.primitives.hashes.SHA1`

SHA-1 is a cryptographic hash function standardized by NIST. It produces an 160-bit message digest. Cryptanalysis of SHA-1 has demonstrated that it is vulnerable to practical collision attacks, and collisions have been demonstrated.

MD5

Warning: MD5 is a deprecated hash algorithm that has practical known collision attacks. You are strongly discouraged from using it. Existing applications should strongly consider moving away.

class `cryptography.hazmat.primitives.hashes.MD5`

MD5 is a deprecated cryptographic hash function. It produces a 128-bit message digest and has practical known collision attacks.

Interfaces

class `cryptography.hazmat.primitives.hashes.HashAlgorithm`

name

Type str

The standard name for the hash algorithm, for example: "sha256" or "whirlpool".

digest_size

Type int

The size of the resulting digest in bytes.

block_size

Type int

The internal block size of the hash algorithm in bytes.

class `cryptography.hazmat.primitives.hashes.HashContext`

algorithm

A *HashAlgorithm* that will be used by this context.

update (*data*)

Parameters *data* (*bytes*) – The data you want to hash.

finalize ()

Returns The final digest as bytes.

copy ()

Returns A *HashContext* that is a copy of the current context.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

You may instead be interested in *Fernet (symmetric encryption)*.

Symmetric encryption

Symmetric encryption is a way to **encrypt** or hide the contents of material where the sender and receiver both use the same secret key. Note that symmetric encryption is **not** sufficient for most applications because it only provides secrecy but not authenticity. That means an attacker can’t see the message but an attacker can create bogus messages and force the application to decrypt them.

For this reason it is **strongly** recommended to combine encryption with a message authentication code, such as *HMAC*, in an “encrypt-then-MAC” formulation as described by Colin Percival. *cryptography* includes a recipe named *Fernet (symmetric encryption)* that does this for you. **To minimize the risk of security issues you should evaluate Fernet to see if it fits your needs before implementing anything using this module.**

class `cryptography.hazmat.primitives.ciphers.Cipher` (*algorithm, mode, backend*)

Cipher objects combine an algorithm such as *AES* with a mode like *CBC* or *CTR*. A simple example of encrypting and then decrypting content with AES is:

```
>>> import os
>>> from cryptography.hazmat.primitives.ciphers import Cipher, algorithms, modes
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> key = os.urandom(32)
>>> iv = os.urandom(16)
>>> cipher = Cipher(algorithms.AES(key), modes.CBC(iv), backend=backend)
>>> encryptor = cipher.encryptor()
>>> ct = encryptor.update(b"a secret message") + encryptor.finalize()
>>> decryptor = cipher.decryptor()
>>> decryptor.update(ct) + decryptor.finalize()
'a secret message'
```

Parameters

- **algorithms** – A *CipherAlgorithm* instance such as those described *below*.
- **mode** – A *Mode* instance such as those described *below*.
- **backend** – A *CipherBackend* instance.

Raises *cryptography.exceptions.UnsupportedAlgorithm* – This is raised if the provided backend does not implement *CipherBackend*

encryptor ()

Returns An encrypting *CipherContext* instance.

If the backend doesn’t support the requested combination of cipher and mode an *UnsupportedAlgorithm* exception will be raised.

decryptor ()

Returns A decrypting *CipherContext* instance.

If the backend doesn't support the requested combination of cipher and mode an `UnsupportedAlgorithm` exception will be raised.

Algorithms

class `cryptography.hazmat.primitives.ciphers.algorithms.AES` (*key*)

AES (Advanced Encryption Standard) is a block cipher standardized by NIST. AES is both fast, and cryptographically strong. It is a good default choice for encryption.

Parameters **key** (*bytes*) – The secret key. This must be kept secret. Either 128, 192, or 256 bits long.

class `cryptography.hazmat.primitives.ciphers.algorithms.Camellia` (*key*)

Camellia is a block cipher approved for use by [CRYPTREC](#) and ISO/IEC. It is considered to have comparable security and performance to AES but is not as widely studied or deployed.

Parameters **key** (*bytes*) – The secret key. This must be kept secret. Either 128, 192, or 256 bits long.

class `cryptography.hazmat.primitives.ciphers.algorithms.TripleDES` (*key*)

Triple DES (Data Encryption Standard), sometimes referred to as 3DES, is a block cipher standardized by NIST. Triple DES has known crypto-analytic flaws, however none of them currently enable a practical attack. Nonetheless, Triple DES is not recommended for new applications because it is incredibly slow; old applications should consider moving away from it.

Parameters **key** (*bytes*) – The secret key. This must be kept secret. Either 64, 128, or 192 bits long. DES only uses 56, 112, or 168 bits of the key as there is a parity byte in each component of the key. Some writing refers to there being up to three separate keys that are each 56 bits long, they can simply be concatenated to produce the full key.

class `cryptography.hazmat.primitives.ciphers.algorithms.CAST5` (*key*)

New in version 0.2.

CAST5 (also known as CAST-128) is a block cipher approved for use in the Canadian government by the [Communications Security Establishment](#). It is a variable key length cipher and supports keys from 40-128 bits in length.

Parameters **key** (*bytes*) – The secret key, This must be kept secret. 40 to 128 bits in length in increments of 8 bits.

class `cryptography.hazmat.primitives.ciphers.algorithms.SEED` (*key*)

New in version 0.4.

SEED is a block cipher developed by the Korea Information Security Agency (KISA). It is defined in [RFC 4269](#) and is used broadly throughout South Korean industry, but rarely found elsewhere.

Parameters **key** (*bytes*) – The secret key. This must be kept secret. 128 bits in length.

Weak ciphers

Warning: These ciphers are considered weak for a variety of reasons. New applications should avoid their use and existing applications should strongly consider migrating away.

class `cryptography.hazmat.primitives.ciphers.algorithms.Blowfish` (*key*)

Blowfish is a block cipher developed by Bruce Schneier. It is known to be susceptible to attacks when using weak keys. The author has recommended that users of Blowfish move to newer algorithms such as [AES](#).

Parameters **key** (*bytes*) – The secret key. This must be kept secret. 32 to 448 bits in length in increments of 8 bits.

class `cryptography.hazmat.primitives.ciphers.algorithms.ARC4` (*key*)
 ARC4 (Alleged RC4) is a stream cipher with serious weaknesses in its initial stream output. Its use is strongly discouraged. ARC4 does not use mode constructions.

Parameters **key** (*bytes*) – The secret key. This must be kept secret. Either 40, 56, 64, 80, 128, 192, or 256 bits in length.

```
>>> from cryptography.hazmat.primitives.ciphers import Cipher, algorithms, modes
>>> from cryptography.hazmat.backends import default_backend
>>> algorithm = algorithms.ARC4(key)
>>> cipher = Cipher(algorithm, mode=None, backend=default_backend())
>>> encryptor = cipher.encryptor()
>>> ct = encryptor.update(b"a secret message")
>>> decryptor = cipher.decryptor()
>>> decryptor.update(ct)
'a secret message'
```

class `cryptography.hazmat.primitives.ciphers.algorithms.IDEA` (*key*)
 IDEA (**I**nternational **D**ata **E**ncryption **A**lgorithm) is a block cipher created in 1991. It is an optional component of the [OpenPGP](#) standard. This cipher is susceptible to attacks when using weak keys. It is recommended that you do not use this cipher for new applications.

Parameters **key** (*bytes*) – The secret key. This must be kept secret. 128 bits in length.

Modes

class `cryptography.hazmat.primitives.ciphers.modes.CBC` (*initialization_vector*)
 CBC (Cipher Block Chaining) is a mode of operation for block ciphers. It is considered cryptographically strong.

Padding is required when using this mode.

Parameters **initialization_vector** (*bytes*) – Must be *random bytes*. They do not need to be kept secret and they can be included in a transmitted message. Must be the same number of bytes as the `block_size` of the cipher. Each time something is encrypted a new `initialization_vector` should be generated. Do not reuse an `initialization_vector` with a given key, and particularly do not use a constant `initialization_vector`.

A good construction looks like:

```
>>> import os
>>> from cryptography.hazmat.primitives.ciphers.modes import CBC
>>> iv = os.urandom(16)
>>> mode = CBC(iv)
```

While the following is bad and will leak information:

```
>>> from cryptography.hazmat.primitives.ciphers.modes import CBC
>>> iv = "a" * 16
>>> mode = CBC(iv)
```

class `cryptography.hazmat.primitives.ciphers.modes.CTR` (*nonce*)

Warning: Counter mode is not recommended for use with block ciphers that have a block size of less than 128-bits.

CTR (Counter) is a mode of operation for block ciphers. It is considered cryptographically strong. It transforms a block cipher into a stream cipher.

This mode does not require padding.

Parameters `nonce` (*bytes*) – Should be unique, a *nonce*. It is critical to never reuse a `nonce` with a given key. Any reuse of a `nonce` with the same key compromises the security of every message encrypted with that key. Must be the same number of bytes as the `block_size` of the cipher with a given key. The `nonce` does not need to be kept secret and may be included with the ciphertext.

class `cryptography.hazmat.primitives.ciphers.modes.OFB` (*initialization_vector*)
OFB (Output Feedback) is a mode of operation for block ciphers. It transforms a block cipher into a stream cipher.

This mode does not require padding.

Parameters `initialization_vector` (*bytes*) – Must be *random bytes*. They do not need to be kept secret and they can be included in a transmitted message. Must be the same number of bytes as the `block_size` of the cipher. Do not reuse an `initialization_vector` with a given key.

class `cryptography.hazmat.primitives.ciphers.modes.CFB` (*initialization_vector*)
CFB (Cipher Feedback) is a mode of operation for block ciphers. It transforms a block cipher into a stream cipher.

This mode does not require padding.

Parameters `initialization_vector` (*bytes*) – Must be *random bytes*. They do not need to be kept secret and they can be included in a transmitted message. Must be the same number of bytes as the `block_size` of the cipher. Do not reuse an `initialization_vector` with a given key.

class `cryptography.hazmat.primitives.ciphers.modes.CFB8` (*initialization_vector*)
CFB (Cipher Feedback) is a mode of operation for block ciphers. It transforms a block cipher into a stream cipher. The CFB8 variant uses an 8-bit shift register.

This mode does not require padding.

Parameters `initialization_vector` (*bytes*) – Must be *random bytes*. They do not need to be kept secret and they can be included in a transmitted message. Must be the same number of bytes as the `block_size` of the cipher. Do not reuse an `initialization_vector` with a given key.

class `cryptography.hazmat.primitives.ciphers.modes.GCM` (*initialization_vector*,
tag=None,
min_tag_length=16)

Danger: When using this mode you **must** not use the decrypted data until the appropriate finalization method (`finalize()` or `finalize_with_tag()`) has been called. GCM provides **no** guarantees of ciphertext integrity until decryption is complete.

GCM (Galois Counter Mode) is a mode of operation for block ciphers. An AEAD (authenticated encryption with additional data) mode is a type of block cipher mode that simultaneously encrypts the message as well

as authenticating it. Additional unencrypted data may also be authenticated. Additional means of verifying integrity such as *HMAC* are not necessary.

This mode does not require padding.

Parameters `initialization_vector` (*bytes*) – Must be unique, a *nonce*. They do not need to be kept secret and they can be included in a transmitted message. NIST recommends a 96-bit IV length for performance critical situations but it can be up to $2^{64} - 1$ bits. Do not reuse an `initialization_vector` with a given key.

Note: Cryptography will generate a 128-bit tag when finalizing encryption. You can shorten a tag by truncating it to the desired length but this is **not recommended** as it lowers the security margins of the authentication (NIST SP-800-38D recommends 96-bits or greater). Applications wishing to allow truncation must pass the `min_tag_length` parameter.

Changed in version 0.5: The `min_tag_length` parameter was added in 0.5, previously truncation down to 4 bytes was always allowed.

Parameters

- **tag** (*bytes*) – The tag bytes to verify during decryption. When encrypting this must be `None`. When decrypting, it may be `None` if the tag is supplied on finalization using `finalize_with_tag()`. Otherwise, the tag is mandatory.
- **min_tag_length** (*bytes*) – The minimum length tag must be. By default this is 16, meaning tag truncation is not allowed. Allowing tag truncation is strongly discouraged for most applications.

Raises

- **ValueError** – This is raised if `len(tag) < min_tag_length`.
- **NotImplementedError** – This is raised if the version of the OpenSSL backend used is 1.0.1 or earlier.

An example of securely encrypting and decrypting data with AES in the GCM mode looks like:

```
import os

from cryptography.hazmat.backends import default_backend
from cryptography.hazmat.primitives.ciphers import (
    Cipher, algorithms, modes
)

def encrypt(key, plaintext, associated_data):
    # Generate a random 96-bit IV.
    iv = os.urandom(12)

    # Construct an AES-GCM Cipher object with the given key and a
    # randomly generated IV.
    encryptor = Cipher(
        algorithms.AES(key),
        modes.GCM(iv),
        backend=default_backend()
    ).encryptor()

    # associated_data will be authenticated but not encrypted,
    # it must also be passed in on decryption.
```

```
encryptor.authenticate_additional_data(associated_data)

# Encrypt the plaintext and get the associated ciphertext.
# GCM does not require padding.
ciphertext = encryptor.update(plaintext) + encryptor.finalize()

return (iv, ciphertext, encryptor.tag)

def decrypt(key, associated_data, iv, ciphertext, tag):
    # Construct a Cipher object, with the key, iv, and additionally the
    # GCM tag used for authenticating the message.
    decryptor = Cipher(
        algorithms.AES(key),
        modes.GCM(iv, tag),
        backend=default_backend()
    ).decryptor()

    # We put associated_data back in or the tag will fail to verify
    # when we finalize the decryptor.
    decryptor.authenticate_additional_data(associated_data)

    # Decryption gets us the authenticated plaintext.
    # If the tag does not match an InvalidTag exception will be raised.
    return decryptor.update(ciphertext) + decryptor.finalize()

iv, ciphertext, tag = encrypt(
    key,
    b"a secret message!",
    b"authenticated but not encrypted payload"
)

print(decrypt(
    key,
    b"authenticated but not encrypted payload",
    iv,
    ciphertext,
    tag
))
```

```
a secret message!
```

Insecure modes

Warning: These modes are insecure. New applications should never make use of them, and existing applications should strongly consider migrating away.

class cryptography.hazmat.primitives.ciphers.modes.ECB

ECB (Electronic Code Book) is the simplest mode of operation for block ciphers. Each block of data is encrypted in the same way. This means identical plaintext blocks will always result in identical ciphertext blocks, which can leave [significant patterns in the output](#).

Padding is required when using this mode.

Interfaces

class `cryptography.hazmat.primitives.ciphers.CipherContext`

When calling `encryptor()` or `decryptor()` on a `Cipher` object the result will conform to the `CipherContext` interface. You can then call `update(data)` with data until you have fed everything into the context. Once that is done call `finalize()` to finish the operation and obtain the remainder of the data.

Block ciphers require that the plaintext or ciphertext always be a multiple of their block size. Because of that **padding** is sometimes required to make a message the correct size. `CipherContext` will not automatically apply any padding; you'll need to add your own. For block ciphers the recommended padding is *PKCS7*. If you are using a stream cipher mode (such as *CTR*) you don't have to worry about this.

`update(data)`

Parameters `data` (*bytes*) – The data you wish to pass into the context.

Return bytes Returns the data that was encrypted or decrypted.

Raises `cryptography.exceptions.AlreadyFinalized` – See `finalize()`

When the `Cipher` was constructed in a mode that turns it into a stream cipher (e.g. *CTR*), this will return bytes immediately, however in other modes it will return chunks whose size is determined by the cipher's block size.

`update_into(data, buf)`

New in version 1.8.

Warning: This method allows you to avoid a memory copy by passing a writable buffer and reading the resulting data. You are responsible for correctly sizing the buffer and properly handling the data. This method should only be used when extremely high performance is a requirement and you will be making many small calls to `update_into`.

Parameters

- `data` (*bytes*) – The data you wish to pass into the context.
- `buf` – A writable Python buffer that the data will be written into. This buffer should be `len(data) + n - 1` bytes where `n` is the block size (in bytes) of the cipher and mode combination.

Return int Number of bytes written.

Raises

- `NotImplementedError` – This is raised if the version of `cffi` used is too old (this can happen on older PyPy releases).
- `ValueError` – This is raised if the supplied buffer is too small.

```
>>> import os
>>> from cryptography.hazmat.primitives.ciphers import Cipher, algorithms, modes
>>> from cryptography.hazmat.backends import default_backend
>>> backend = default_backend()
>>> key = os.urandom(32)
>>> iv = os.urandom(16)
>>> cipher = Cipher(algorithms.AES(key), modes.CBC(iv), backend=backend)
>>> encryptor = cipher.encryptor()
```

```

>>> # the buffer needs to be at least len(data) + n - 1 where n is cipher/
↳mode block size in bytes
>>> buf = bytearray(31)
>>> len_encrypted = encryptor.update_into(b"a secret message", buf)
>>> # get the ciphertext from the buffer reading only the bytes written to it,
↳(len_encrypted)
>>> ct = bytes(buf[:len_encrypted]) + encryptor.finalize()
>>> decryptor = cipher.decryptor()
>>> len_decrypted = decryptor.update_into(ct, buf)
>>> # get the plaintext from the buffer reading only the bytes written (len_
↳decrypted)
>>> bytes(buf[:len_decrypted]) + decryptor.finalize()
'a secret message'

```

finalize()

Return bytes Returns the remainder of the data.

Raises `ValueError` – This is raised when the data provided isn't a multiple of the algorithm's block size.

Once `finalize` is called this object can no longer be used and `update()` and `finalize()` will raise an `AlreadyFinalized` exception.

class `cryptography.hazmat.primitives.ciphers.AEADCipherContext`

When calling `encryptor` or `decryptor` on a `Cipher` object with an AEAD mode (e.g. `GCM`) the result will conform to the `AEADCipherContext` and `CipherContext` interfaces. If it is an encryption or decryption context it will additionally be an `AEADEncryptionContext` or `AEADDecryptionContext` instance, respectively. `AEADCipherContext` contains an additional method `authenticate_additional_data()` for adding additional authenticated but unencrypted data (see note below). You should call this before calls to `update`. When you are done call `finalize` to finish the operation.

Note: In AEAD modes all data passed to `update()` will be both encrypted and authenticated. Do not pass encrypted data to the `authenticate_additional_data()` method. It is meant solely for additional data you may want to authenticate but leave unencrypted.

authenticate_additional_data(data)

Parameters `data` (*bytes*) – Any data you wish to authenticate but not encrypt.

Raises `AlreadyFinalized`

class `cryptography.hazmat.primitives.ciphers.AEADEncryptionContext`

When creating an encryption context using `encryptor` on a `Cipher` object with an AEAD mode such as `GCM` an object conforming to both the `AEADEncryptionContext` and `AEADCipherContext` interfaces will be returned. This interface provides one additional attribute `tag`. `tag` can only be obtained after `finalize` has been called.

tag

Return bytes Returns the tag value as bytes.

Raises `NotYetFinalized` if called before the context is finalized.

class `cryptography.hazmat.primitives.ciphers.AEADDecryptionContext`

New in version 1.9.

When creating an encryption context using `decryptor` on a `Cipher` object with an AEAD mode such as `GCM` an object conforming to both the `AEADDecryptionContext` and `AEADCipherContext` interfaces

will be returned. This interface provides one additional method `finalize_with_tag()` that allows passing the authentication tag for validation after the ciphertext has been decrypted.

finalize_with_tag (*tag*)

Note: This method is not supported when compiled against OpenSSL 1.0.1.

Parameters **tag** (*bytes*) – The tag bytes to verify after decryption.

Return bytes Returns the remainder of the data.

Raises

- **ValueError** – This is raised when the data provided isn’t a multiple of the algorithm’s block size, if `min_tag_length` is less than 4, or if `len(tag) < min_tag_length`.
- **NotImplementedError** – This is raised if the version of the OpenSSL backend used is 1.0.1 or earlier.

If the authentication tag was not already supplied to the constructor of the *GCM* mode object, this method must be used instead of `finalize()`.

class `cryptography.hazmat.primitives.ciphers.CipherAlgorithm`

A named symmetric encryption algorithm.

name

Type `str`

The standard name for the mode, for example, “AES”, “Camellia”, or “Blowfish”.

key_size

Type `int`

The number of bits in the key being used.

class `cryptography.hazmat.primitives.ciphers.BlockCipherAlgorithm`

A block cipher algorithm.

block_size

Type `int`

The number of bits in a block.

Interfaces used by the symmetric cipher modes described in *Symmetric Encryption Modes*.

class `cryptography.hazmat.primitives.ciphers.modes.Mode`

A named cipher mode.

name

Type `str`

This should be the standard shorthand name for the mode, for example Cipher-Block Chaining mode is “CBC”.

The name may be used by a backend to influence the operation of a cipher in conjunction with the algorithm’s name.

validate_for_algorithm (*algorithm*)

Parameters `algorithm` (`cryptography.hazmat.primitives.ciphers.CipherAlgorithm`) –

Checks that the combination of this mode with the provided algorithm meets any necessary invariants. This should raise an exception if they are not met.

For example, the `CBC` mode uses this method to check that the provided initialization vector's length matches the block size of the algorithm.

class `cryptography.hazmat.primitives.ciphers.modes.ModeWithInitializationVector`
A cipher mode with an initialization vector.

initialization_vector

Type bytes

Exact requirements of the initialization are described by the documentation of individual modes.

class `cryptography.hazmat.primitives.ciphers.modes.ModeWithNonce`
A cipher mode with a nonce.

nonce

Type bytes

Exact requirements of the nonce are described by the documentation of individual modes.

class `cryptography.hazmat.primitives.ciphers.modes.ModeWithAuthenticationTag`
A cipher mode with an authentication tag.

tag

Type bytes

Exact requirements of the tag are described by the documentation of individual modes.

Exceptions

class `cryptography.exceptions.InvalidTag`
This is raised if an authenticated encryption tag fails to verify during decryption.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Symmetric Padding

Padding is a way to take data that may or may not be a multiple of the block size for a cipher and extend it out so that it is. This is required for many block cipher modes as they require the data to be encrypted to be an exact multiple of the block size.

class `cryptography.hazmat.primitives.padding.PKCS7` (*block_size*)
PKCS7 padding is a generalization of PKCS5 padding (also known as standard padding). PKCS7 padding works by appending N bytes with the value of `chr(N)`, where N is the number of bytes required to make the final block of data the same size as the block size. A simple example of padding is:

```
>>> from cryptography.hazmat.primitives import padding
>>> padder = padding.PKCS7(128).padder()
>>> padded_data = padder.update(b"111111111111111111112222222222")
```

```

>>> padded_data
'11111111111111111111'
>>> padded_data += padder.finalize()
>>> padded_data
'111111111111111111112222222222\x06\x06\x06\x06\x06\x06'
>>> unpadder = padding.PKCS7(128).unpadder()
>>> data = unpadder.update(padded_data)
>>> data
'11111111111111111111'
>>> data + unpadder.finalize()
'111111111111111111112222222222'

```

Parameters `block_size` – The size of the block in bits that the data is being padded to.

Raises `ValueError` – Raised if block size is not a multiple of 8 or is not between 0 and 2040 inclusive.

`padder()`

Returns A padding `PaddingContext` instance.

`unpadder()`

Returns An unpadding `PaddingContext` instance.

class `cryptography.hazmat.primitives.padding.ANSIX923` (*block_size*)
New in version 1.3.

ANSI X.923 padding works by appending $N-1$ bytes with the value of 0 and a last byte with the value of `chr(N)`, where N is the number of bytes required to make the final block of data the same size as the block size. A simple example of padding is:

```

>>> padder = padding.ANSIX923(128).padder()
>>> padded_data = padder.update(b"111111111111111111112222222222")
>>> padded_data
'11111111111111111111'
>>> padded_data += padder.finalize()
>>> padded_data
'111111111111111111112222222222\x00\x00\x00\x00\x00\x06'
>>> unpadder = padding.ANSIX923(128).unpadder()
>>> data = unpadder.update(padded_data)
>>> data
'11111111111111111111'
>>> data + unpadder.finalize()
'111111111111111111112222222222'

```

Parameters `block_size` – The size of the block in bits that the data is being padded to.

Raises `ValueError` – Raised if block size is not a multiple of 8 or is not between 0 and 2040 inclusive.

`padder()`

Returns A padding `PaddingContext` instance.

`unpadder()`

Returns An unpadding `PaddingContext` instance.

class `cryptography.hazmat.primitives.padding.PaddingContext`

When calling `padder()` or `unpadder()` the result will conform to the `PaddingContext` interface. You can then call `update(data)` with data until you have fed everything into the context. Once that is done call `finalize()` to finish the operation and obtain the remainder of the data.

update (*data*)

Parameters *data* (*bytes*) – The data you wish to pass into the context.

Return bytes Returns the data that was padded or unpadded.

Raises

- **TypeError** – Raised if data is not bytes.
- `cryptography.exceptions.AlreadyFinalized` – See `finalize()`.
- **TypeError** – This exception is raised if data is not bytes.

finalize ()

Finalize the current context and return the rest of the data.

After `finalize` has been called this object can no longer be used; `update()` and `finalize()` will raise an `AlreadyFinalized` exception.

Return bytes Returns the remainder of the data.

Raises

- **TypeError** – Raised if data is not bytes.
- **ValueError** – When trying to remove padding from incorrectly padded data.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Two-factor authentication

This module contains algorithms related to two-factor authentication.

Currently, it contains an algorithm for generating and verifying one time password values based on Hash-based message authentication codes (HMAC).

class `cryptography.hazmat.primitives.twofactor.InvalidToken`

This is raised when the verify method of a one time password function’s computed token does not match the expected token.

class `cryptography.hazmat.primitives.twofactor.hotp.HOTP` (*key*, *length*, *algorithm*, *backend*, *enforce_key_length=True*)

New in version 0.3.

HOTP objects take a *key*, *length* and *algorithm* parameter. The *key* should be *randomly generated bytes* and is recommended to be 160 bits in length. The *length* parameter controls the length of the generated one time password and must be ≥ 6 and ≤ 8 .

This is an implementation of [RFC 4226](#).

```

>>> import os
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives.twofactor.hotp import HOTP
>>> from cryptography.hazmat.primitives.hashes import SHA1
>>> key = os.urandom(20)
>>> hotp = HOTP(key, 6, SHA1(), backend=default_backend())
>>> hotp_value = hotp.generate(0)
>>> hotp.verify(hotp_value, 0)

```

Parameters

- **key** (*bytes*) – Per-user secret key. This value must be kept secret and be at least 128 bits. It is recommended that the key be 160 bits.
- **length** (*int*) – Length of generated one time password as *int*.
- **algorithm** (*cryptography.hazmat.primitives.hashes.HashAlgorithm*) – A *hashes* instance.
- **backend** – A *HMACHBackend* instance.
- **enforce_key_length** – A boolean flag defaulting to True that toggles whether a minimum key length of 128 bits is enforced. This exists to work around the fact that as documented in [Issue #2915](#), the Google Authenticator PAM module by default generates 80 bit keys. If this flag is set to False, the application developer should implement additional checks of the key length before passing it into *HOTP*.

New in version 1.5.

Raises

- **ValueError** – This is raised if the provided key is shorter than 128 bits or if the length parameter is not 6, 7 or 8.
- **TypeError** – This is raised if the provided algorithm is not *SHA1()*, *SHA256()* or *SHA512()* or if the length parameter is not an integer.
- ***cryptography.exceptions.UnsupportedAlgorithm*** – This is raised if the provided backend does not implement *HMACHBackend*

generate (*counter*)

Parameters **counter** (*int*) – The counter value used to generate the one time password.

Return bytes A one time password value.

verify (*hotp, counter*)

Parameters

- **hotp** (*bytes*) – The one time password value to validate.
- **counter** (*int*) – The counter value to validate against.

Raises ***cryptography.hazmat.primitives.twofactor.InvalidToken*** – This is raised when the supplied HOTP does not match the expected HOTP.

get_provisioning_uri (*account_name, counter, issuer*)

New in version 1.0.

Parameters

- **account_name** (*text*) – The display name of account, such as 'Alice Smith' or 'alice@example.com'.
- **issuer** (*text* or *None*) – The optional display name of issuer. This is typically the provider or service the user wants to access using the OTP token.
- **counter** (*int*) – The current value of counter.

Returns A URI string.

Throttling

Due to the fact that the HOTP algorithm generates rather short tokens that are 6 - 8 digits long, brute force attacks are possible. It is highly recommended that the server that validates the token implement a throttling scheme that locks out the account for a period of time after a number of failed attempts. The number of allowed attempts should be as low as possible while still ensuring that usability is not significantly impacted.

Re-synchronization of the counter

The server's counter value should only be incremented on a successful HOTP authentication. However, the counter on the client is incremented every time a new HOTP value is requested. This can lead to the counter value being out of synchronization between the client and server.

Due to this, it is highly recommended that the server sets a look-ahead window that allows the server to calculate the next x HOTP values and check them against the supplied HOTP value. This can be accomplished with something similar to the following code.

```
def verify(hotp, counter, look_ahead):
    assert look_ahead >= 0
    correct_counter = None

    otp = HOTP(key, 6, default_backend())
    for count in range(counter, counter + look_ahead):
        try:
            otp.verify(hotp, count)
            correct_counter = count
        except InvalidToken:
            pass

    return correct_counter
```

```
class cryptography.hazmat.primitives.twofactor.totp.TOTP(key, length, algorithm,
                                                         time_step, backend, enforce_key_length=True)
```

TOTP objects take a key, length, algorithm and time_step parameter. The key should be *randomly generated bytes* and is recommended to be as long as your hash function's output (e.g 256-bit for SHA256). The length parameter controls the length of the generated one time password and must be ≥ 6 and ≤ 8 .

This is an implementation of [RFC 6238](#).

```
>>> import os
>>> import time
>>> from cryptography.hazmat.backends import default_backend
>>> from cryptography.hazmat.primitives.twofactor.totp import TOTP
>>> from cryptography.hazmat.primitives.hashes import SHA1
>>> key = os.urandom(20)
>>> totp = TOTP(key, 8, SHA1(), 30, backend=default_backend())
```

```
>>> time_value = time.time()
>>> totp_value = totp.generate(time_value)
>>> totp.verify(totp_value, time_value)
```

Parameters

- **key** (*bytes*) – Per-user secret key. This value must be kept secret and be at least 128 bits. It is recommended that the key be 160 bits.
- **length** (*int*) – Length of generated one time password as *int*.
- **algorithm** (*cryptography.hazmat.primitives.hashes.HashAlgorithm*) – A *hashes* instance.
- **time_step** (*int*) – The time step size. The recommended size is 30.
- **backend** – A *HMACBackend* instance.
- **enforce_key_length** – A boolean flag defaulting to True that toggles whether a minimum key length of 128 bits is enforced. This exists to work around the fact that as documented in [Issue #2915](#), the Google Authenticator PAM module by default generates 80 bit keys. If this flag is set to False, the application developer should implement additional checks of the key length before passing it into *TOTP*.

New in version 1.5.

Raises

- **ValueError** – This is raised if the provided key is shorter than 128 bits or if the length parameter is not 6, 7 or 8.
- **TypeError** – This is raised if the provided algorithm is not *SHA1()*, *SHA256()* or *SHA512()* or if the length parameter is not an integer.
- **cryptography.exceptions.UnsupportedAlgorithm** – This is raised if the provided backend does not implement *HMACBackend*

generate(*time*)

Parameters *time* (*int*) – The time value used to generate the one time password.

Return bytes A one time password value.

verify(*totp*, *time*)

Parameters

- **totp** (*bytes*) – The one time password value to validate.
- **time** (*int*) – The time value to validate against.

Raises *cryptography.hazmat.primitives.twofactor.InvalidToken* – This is raised when the supplied TOTP does not match the expected TOTP.

get_provisioning_uri(*account_name*, *issuer*)

New in version 1.0.

Parameters

- **account_name** – The display name of account, such as 'Alice Smith' or 'alice@example.com'.
- **issuer** (*text* or *None*) – The optional display name of issuer. This is typically the provider or service the user wants to access using the OTP token.

Type *text*

Returns A URI string.

Provisioning URI

The provisioning URI of HOTP and TOTP is not actual the part of RFC 4226 and RFC 6238, but a [spec of Google Authenticator](#). It is widely supported by web sites and mobile applications which are using Two-Factor authentication.

For generating a provisioning URI, you could use the `get_provisioning_uri` method of HOTP/TOTP instances.

```
counter = 5
account_name = 'alice@example.com'
issuer_name = 'Example Inc'

hotp_uri = hotp.get_provisioning_uri(account_name, counter, issuer_name)
totp_uri = totp.get_provisioning_uri(account_name, issuer_name)
```

A common usage is encoding the provisioning URI into QR code and guiding users to scan it with Two-Factor authentication applications in their mobile devices.

Exceptions

class `cryptography.exceptions.UnsupportedAlgorithm`

Raised when the requested algorithm, or combination of algorithms is not supported.

class `cryptography.exceptions.AlreadyFinalized`

This is raised when a context is used after being finalized.

class `cryptography.exceptions.InvalidSignature`

This is raised when signature verification fails. This can occur with HMAC or asymmetric key signature validation.

class `cryptography.exceptions.NotYetFinalized`

This is raised when the AEAD tag property is accessed on a context before it is finalized.

class `cryptography.exceptions.AlreadyUpdated`

This is raised when additional data is added to a context after update has already been called.

class `cryptography.exceptions.InvalidKey`

This is raised when the verify method of a key derivation function's computed key does not match the expected key.

Random number generation

When generating random data for use in cryptographic operations, such as an initialization vector for encryption in *CBC* mode, you do not want to use the standard `random` module APIs. This is because they do not provide a cryptographically secure random number generator, which can result in major security issues depending on the algorithms in use.

Therefore, it is our recommendation to always use your operating system's provided random number generator, which is available as `os.urandom()`. For example, if you need 16 bytes of random data for an initialization vector, you can obtain them with:

```
>>> import os
>>> iv = os.urandom(16)
```

This will use `/dev/urandom` on UNIX platforms, and `CryptGenRandom` on Windows.

If you need your random number as an integer (for example, for `serial_number()`), you can use `int.from_bytes` to convert the result of `os.urandom`:

```
>>> serial = int.from_bytes(os.urandom(20), byteorder="big")
```

Starting with Python 3.6 the standard library includes the `secrets` module, which can be used for generating cryptographically secure random numbers, with specific helpers for text-based formats.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Backends

Getting a backend

`cryptography` was originally designed to support multiple backends, but this design has been deprecated.

You can get the default backend by calling `default_backend()`.

```
cryptography.hazmat.backends.default_backend()
```

Returns An object that provides at least `CipherBackend`, `HashBackend`, and `HMACBackend`.

Individual backends

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

OpenSSL backend

The `OpenSSL` C library. Cryptography supports `OpenSSL` version 1.0.1 and greater.

```
cryptography.hazmat.backends.openssl.backend
```

This is the exposed API for the `OpenSSL` backend.

It implements the following interfaces:

- `CipherBackend`
- `CMACBackend`
- `DERSerializationBackend`
- `DHBackend`

- DSABackend*
- EllipticCurveBackend*
- HashBackend*
- HMACBackend*
- PBKDF2HMACBackend*
- RSABackend*
- PEMSerializationBackend*
- X509Backend*

It also implements the following interface for OpenSSL versions 1.1.0 and above.

- ScryptBackend*

It also exposes the following:

name

The string name of this backend: "openssl"

openssl_version_text ()

Return text The friendly string name of the loaded OpenSSL library. This is not necessarily the same version as it was compiled against.

openssl_version_number ()

New in version 1.8.

Return int The integer version of the loaded OpenSSL library. This is defined in `opensslv.h` as `OPENSSL_VERSION_NUMBER` and is typically shown in hexadecimal (e.g. `0x1010003f`). This is not necessarily the same version as it was compiled against.

activate_osrandom_engine ()

Activates the OS random engine. This will effectively disable OpenSSL's default CSPRNG.

osrandom_engine_implementation ()

New in version 1.7.

Returns the implementation of OS random engine.

activate_builtin_random ()

This will activate the default OpenSSL CSPRNG.

OS random engine

By default OpenSSL uses a user-space CSPRNG that is seeded from system random (`/dev/urandom` or `CryptGenRandom`). This CSPRNG is not reseeded automatically when a process calls `fork()`. This can result in situations where two different processes can return similar or identical keys and compromise the security of the system.

The approach this project has chosen to mitigate this vulnerability is to include an engine that replaces the OpenSSL default CSPRNG with one that sources its entropy from `/dev/urandom` on UNIX-like operating systems and uses `CryptGenRandom` on Windows. This method of pulling from the system pool allows us to avoid potential issues with [initializing the RNG](#) as well as protecting us from the `fork()` weakness.

This engine is **active** by default when importing the OpenSSL backend. When active this engine will be used to generate all the random data OpenSSL requests.

When importing only the binding it is added to the engine list but **not activated**.

OS random sources

On macOS and FreeBSD `/dev/urandom` is an alias for `/dev/random`. The implementation on macOS uses the [Yarrow](#) algorithm. FreeBSD uses the [Fortuna](#) algorithm.

On Windows the implementation of `CryptGenRandom` depends on which version of the operation system you are using. See the [Microsoft documentation](#) for more details.

Linux uses its own PRNG design. `/dev/urandom` is a non-blocking source seeded from the same pool as `/dev/random`.

Windows	<code>CryptGenRandom()</code>
Linux >= 3.4.17 with working <code>SYS_getrandom</code> syscall	<code>getrandom(GRND_NONBLOCK)</code>
OpenBSD >= 5.6	<code>getentropy()</code>
BSD family (including macOS 10.12+) with <code>SYS_getentropy</code> in <code>sys/syscall.h</code>	<code>getentropy()</code>
fallback	<code>/dev/urandom</code> with cached file descriptor

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Backend interfaces

Backend implementations may provide a number of interfaces to support operations such as *Symmetric encryption*, *Message digests (Hashing)*, and *Hash-based message authentication codes (HMAC)*.

A specific backend may provide one or more of these interfaces.

class `cryptography.hazmat.backends.interfaces.CipherBackend`

A backend that provides methods for using ciphers for encryption and decryption.

The following backends implement this interface:

- *OpenSSL backend*

cipher_supported (*cipher*, *mode*)

Check if a `cipher` and `mode` combination is supported by this backend.

Parameters

- **cipher** – An instance of *CipherAlgorithm*.
- **mode** – An instance of *Mode*.

Returns True if the specified `cipher` and `mode` combination is supported by this backend, otherwise False

create_symmetric_encryption_ctx (*cipher*, *mode*)

Create a *CipherContext* that can be used for encrypting data with the symmetric `cipher` using the given `mode`.

Parameters

- **cipher** – An instance of *CipherAlgorithm*.
- **mode** – An instance of *Mode*.

Returns *CipherContext*

Raises `ValueError` – When tag is not None in an AEAD mode

`create_symmetric_decryption_ctx` (*cipher*, *mode*)

Create a `CipherContext` that can be used for decrypting data with the symmetric `cipher` using the given `mode`.

Parameters

- `cipher` – An instance of `CipherAlgorithm`.
- `mode` – An instance of `Mode`.

Returns `CipherContext`

Raises `ValueError` – When tag is None in an AEAD mode

class `cryptography.hazmat.backends.interfaces.HashBackend`

A backend with methods for using cryptographic hash functions.

The following backends implement this interface:

- `OpenSSL backend`

`hash_supported` (*algorithm*)

Check if the specified `algorithm` is supported by this backend.

Parameters `algorithm` – An instance of `HashAlgorithm`.

Returns True if the specified `algorithm` is supported by this backend, otherwise False.

`create_hash_ctx` (*algorithm*)

Create a `HashContext` that uses the specified `algorithm` to calculate a message digest.

Parameters `algorithm` – An instance of `HashAlgorithm`.

Returns `HashContext`

class `cryptography.hazmat.backends.interfaces.HMACBackend`

A backend with methods for using cryptographic hash functions as message authentication codes.

The following backends implement this interface:

- `OpenSSL backend`

`hmac_supported` (*algorithm*)

Check if the specified `algorithm` is supported by this backend.

Parameters `algorithm` – An instance of `HashAlgorithm`.

Returns True if the specified `algorithm` is supported for HMAC by this backend, otherwise False.

`create_hmac_ctx` (*key*, *algorithm*)

Create a `HashContext` that uses the specified `algorithm` to calculate a hash-based message authentication code.

Parameters

- `key` (*bytes*) – Secret key as bytes.
- `algorithm` – An instance of `HashAlgorithm`.

Returns `HashContext`

class `cryptography.hazmat.backends.interfaces.CMACBackend`

New in version 0.4.

A backend with methods for using CMAC

cmac_algorithm_supported (*algorithm*)

Parameters *algorithm* – An instance of *BlockCipherAlgorithm*.

Returns Returns True if the block cipher is supported for CMAC by this backend

create_cmac_ctx (*algorithm*)

Create a *MACContext* that uses the specified algorithm to calculate a message authentication code.

Parameters *algorithm* – An instance of *BlockCipherAlgorithm*.

Returns *MACContext*

class `cryptography.hazmat.backends.interfaces.PBKDF2HMACBackend`
New in version 0.2.

A backend with methods for using PBKDF2 using HMAC as a PRF.

The following backends implement this interface:

- *OpenSSL backend*

pbkdf2_hmac_supported (*algorithm*)

Check if the specified algorithm is supported by this backend.

Parameters *algorithm* – An instance of *HashAlgorithm*.

Returns True if the specified algorithm is supported for PBKDF2 HMAC by this backend, otherwise False.

derive_pbkdf2_hmac (*self, algorithm, length, salt, iterations, key_material*)

Parameters

- **algorithm** – An instance of *HashAlgorithm*.
- **length** (*int*) – The desired length of the derived key. Maximum is $(2^{32} - 1) * \text{algorithm.digest_size}$
- **salt** (*bytes*) – A salt.
- **iterations** (*int*) – The number of iterations to perform of the hash function. This can be used to control the length of time the operation takes. Higher numbers help mitigate brute force attacks against derived keys.
- **key_material** (*bytes*) – The key material to use as a basis for the derived key. This is typically a password.

Return bytes Derived key.

class `cryptography.hazmat.backends.interfaces.RSABackend`
New in version 0.2.

A backend with methods for using RSA.

generate_rsa_private_key (*public_exponent, key_size*)

Parameters

- **public_exponent** (*int*) – The public exponent of the new key. Often one of the small Fermat primes 3, 5, 17, 257 or 65537.
- **key_size** (*int*) – The length in bits of the modulus. Should be at least 2048.

Returns A new instance of *RSAPrivateKey*.

Raises **ValueError** – If the public_exponent is not valid.

rsa_padding_supported (*padding*)

Check if the specified *padding* is supported by the backend.

Parameters *padding* – An instance of *AsymmetricPadding*.

Returns True if the specified *padding* is supported by this backend, otherwise False.

generate_rsa_parameters_supported (*public_exponent*, *key_size*)

Check if the specified parameters are supported for key generation by the backend.

Parameters

- **public_exponent** (*int*) – The public exponent.
- **key_size** (*int*) – The bit length of the generated modulus.

load_rsa_private_numbers (*numbers*)

Parameters *numbers* – An instance of *RSAPrivateNumbers*.

Returns An instance of *RSAPrivateKey*.

Raises

- **ValueError** – This is raised when the values of *p*, *q*, *private_exponent*, *public_exponent*, or *modulus* do not match the bounds specified in [RFC 3447](#).
- ***cryptography.exceptions.UnsupportedAlgorithm*** – This is raised when any backend specific criteria are not met.

load_rsa_public_numbers (*numbers*)

Parameters *numbers* – An instance of *RSAPrivateNumbers*.

Returns An instance of *RSAPublicKey*.

Raises

- **ValueError** – This is raised when the values of *public_exponent* or *modulus* do not match the bounds specified in [RFC 3447](#).
- ***cryptography.exceptions.UnsupportedAlgorithm*** – This is raised when any backend specific criteria are not met.

class `cryptography.hazmat.backends.interfaces.DSABackend`

New in version 0.4.

A backend with methods for using DSA.

generate_dsa_parameters (*key_size*)

Parameters *key_size* (*int*) – The length of the modulus in bits. It should be either 1024, 2048 or 3072. For keys generated in 2015 this should be at least 2048. Note that some applications (such as SSH) have not yet gained support for larger key sizes specified in FIPS 186-3 and are still restricted to only the 1024-bit keys specified in FIPS 186-2.

Returns A new instance of *DSAParameters*.

generate_dsa_private_key (*parameters*)

Parameters *parameters* – An instance of *DSAParameters*.

Returns A new instance of *DSAPrivateKey*.

Raises **ValueError** – This is raised if the key size is not one of 1024, 2048, or 3072.

generate_dsa_private_key_and_parameters (*key_size*)

Parameters `key_size` (*int*) – The length of the modulus in bits. It should be either 1024, 2048 or 3072. For keys generated in 2015 this should be at least 2048. Note that some applications (such as SSH) have not yet gained support for larger key sizes specified in FIPS 186-3 and are still restricted to only the 1024-bit keys specified in FIPS 186-2.

Returns A new instance of *DSAPrivateKey*.

Raises `ValueError` – This is raised if the key size is not supported by the backend.

dsa_hash_supported (*algorithm*)

Parameters `algorithm` – An instance of *HashAlgorithm*.

Returns True if the specified algorithm is supported by this backend, otherwise False.

dsa_parameters_supported (*p, q, g*)

Parameters

- `p` (*int*) – The p value of a DSA key.
- `q` (*int*) – The q value of a DSA key.
- `g` (*int*) – The g value of a DSA key.

Returns True if the given values of p, q, and g are supported by this backend, otherwise False.

load_dsa_parameter_numbers (*numbers*)

Parameters `numbers` – An instance of *DSAPrivateNumbers*.

Returns An instance of *DSAPrivateNumbers*.

Raises `cryptography.exceptions.UnsupportedAlgorithm` – This is raised when any backend specific criteria are not met.

load_dsa_private_numbers (*numbers*)

Parameters `numbers` – An instance of *DSAPrivateNumbers*.

Returns An instance of *DSAPrivateKey*.

Raises `cryptography.exceptions.UnsupportedAlgorithm` – This is raised when any backend specific criteria are not met.

load_dsa_public_numbers (*numbers*)

Parameters `numbers` – An instance of *DSAPublicNumbers*.

Returns An instance of *DSAPublicKey*.

Raises `cryptography.exceptions.UnsupportedAlgorithm` – This is raised when any backend specific criteria are not met.

class `cryptography.hazmat.backends.interfaces.EllipticCurveBackend`

New in version 0.5.

elliptic_curve_supported (*curve*)

Parameters `curve` – An instance of *EllipticCurve*.

Returns True if the elliptic curve is supported by this backend.

elliptic_curve_signature_algorithm_supported (*signature_algorithm, curve*)

Parameters

- `signature_algorithm` – An instance of *EllipticCurveSignatureAlgorithm*.

- **curve** – An instance of *EllipticCurve*.

Returns True if the signature algorithm and curve are supported by this backend.

generate_elliptic_curve_private_key (*curve*)

Parameters **curve** – An instance of *EllipticCurve*.

load_elliptic_curve_private_numbers (*numbers*)

Parameters **numbers** – An instance of *EllipticCurvePrivateNumbers*.

Returns An instance of *EllipticCurvePrivateKey*.

load_elliptic_curve_public_numbers (*numbers*)

Parameters **numbers** – An instance of *EllipticCurvePublicNumbers*.

Returns An instance of *EllipticCurvePublicKey*.

derive_elliptic_curve_private_key (*private_value*, *curve*)

Parameters

- **private_value** – A secret scalar value.
- **curve** – An instance of *EllipticCurve*.

Returns An instance of *EllipticCurvePrivateKey*.

class `cryptography.hazmat.backends.interfaces.PEMSerializationBackend`

New in version 0.6.

A backend with methods for working with any PEM encoded keys.

load_pem_private_key (*data*, *password*)

Parameters

- **data** (*bytes*) – PEM data to load.
- **password** (*bytes*) – The password to use if the data is encrypted. Should be `None` if the data is not encrypted.

Returns A new instance of the appropriate type of private key that the serialized data contains.

Raises

- **ValueError** – If the data could not be deserialized.
- `cryptography.exceptions.UnsupportedAlgorithm` – If the data is encrypted with an unsupported algorithm.

load_pem_public_key (*data*)

Parameters **data** (*bytes*) – PEM data to load.

Returns A new instance of the appropriate type of public key serialized data contains.

Raises **ValueError** – If the data could not be deserialized.

class `cryptography.hazmat.backends.interfaces.DERSerializationBackend`

New in version 0.8.

A backend with methods for working with DER encoded keys.

load_der_private_key (*data*, *password*)

Parameters

- **data** (*bytes*) – DER data to load.
- **password** (*bytes*) – The password to use if the data is encrypted. Should be `None` if the data is not encrypted.

Returns A new instance of the appropriate type of private key that the serialized data contains.

Raises

- **ValueError** – If the data could not be deserialized.
- `cryptography.exceptions.UnsupportedAlgorithm` – If the data is encrypted with an unsupported algorithm.

load_der_public_key (*data*)

Parameters **data** (*bytes*) – DER data to load.

Returns A new instance of the appropriate type of public key serialized data contains.

Raises **ValueError** – If the data could not be deserialized.

class `cryptography.hazmat.backends.interfaces.X509Backend`
New in version 0.7.

A backend with methods for working with X.509 objects.

load_pem_x509_certificate (*data*)

Parameters **data** (*bytes*) – PEM formatted certificate data.

Returns An instance of `Certificate`.

load_der_x509_certificate (*data*)

Parameters **data** (*bytes*) – DER formatted certificate data.

Returns An instance of `Certificate`.

load_pem_x509_csr (*data*)

New in version 0.9.

Parameters **data** (*bytes*) – PEM formatted certificate signing request data.

Returns An instance of `CertificateSigningRequest`.

load_der_x509_csr (*data*)

New in version 0.9.

Parameters **data** (*bytes*) – DER formatted certificate signing request data.

Returns An instance of `CertificateSigningRequest`.

create_x509_csr (*builder, private_key, algorithm*)

New in version 1.0.

Parameters

- **builder** – An instance of `CertificateSigningRequestBuilder`.
- **private_key** – The `RSAPrivateKey`, `DSAPrivateKey` or `EllipticCurvePrivateKey` that will be used to sign the request. When the request is signed by a certificate authority, the private key’s associated public key will be stored in the resulting certificate.
- **algorithm** – The `HashAlgorithm` that will be used to generate the request signature.

Returns A new instance of `CertificateSigningRequest`.

create_x509_certificate (*builder, private_key, algorithm*)

New in version 1.0.

Parameters

- **builder** – An instance of *CertificateBuilder*.
- **private_key** – The *RSAPrivateKey*, *DSAPrivateKey* or *EllipticCurvePrivateKey* that will be used to sign the certificate.
- **algorithm** – The *HashAlgorithm* that will be used to generate the certificate signature.

Returns A new instance of *Certificate*.

create_x509_crl (*builder, private_key, algorithm*)

New in version 1.2.

Parameters

- **builder** – An instance of *CertificateRevocationListBuilder*.
- **private_key** – The *RSAPrivateKey*, *DSAPrivateKey* or *EllipticCurvePrivateKey* that will be used to sign the CRL.
- **algorithm** – The *HashAlgorithm* that will be used to generate the CRL signature.

Returns A new instance of *CertificateRevocationList*.

create_x509_revoked_certificate (*builder*)

New in version 1.2.

Parameters **builder** – An instance of *RevokedCertificateBuilder*.

Returns A new instance of *RevokedCertificate*.

x509_name_bytes (*name*)

New in version 1.6.

Parameters **name** – An instance of *Name*.

Return bytes The DER encoded bytes.

class `cryptography.hazmat.backends.interfaces.DHBackend`

New in version 0.9.

A backend with methods for doing Diffie-Hellman key exchange.

generate_dh_parameters (*generator, key_size*)

Parameters

- **generator** (*int*) – The generator to use. Often 2 or 5.
- **key_size** (*int*) – The bit length of the prime modulus to generate.

Returns A new instance of *DHParameters*.

Raises **ValueError** – If *key_size* is not at least 512.

generate_dh_private_key (*parameters*)

Parameters **parameters** – An instance of *DHParameters*.

Returns A new instance of *DHPrivateKey*.

generate_dh_private_key_and_parameters (*generator, key_size*)

Parameters

- **generator** (*int*) – The generator to use. Often 2 or 5.
- **key_size** (*int*) – The bit length of the prime modulus to generate.

Returns A new instance of *DHPrivateKey*.

Raises **ValueError** – If *key_size* is not at least 512.

load_dh_private_numbers (*numbers*)

Parameters **numbers** – A *DHPrivateNumbers* instance.

Returns A new instance of *DHPrivateKey*.

Raises *cryptography.exceptions.UnsupportedAlgorithm* – This is raised when any backend specific criteria are not met.

load_dh_public_numbers (*numbers*)

Parameters **numbers** – A *DHPublicNumbers* instance.

Returns A new instance of *DHPublicKey*.

Raises *cryptography.exceptions.UnsupportedAlgorithm* – This is raised when any backend specific criteria are not met.

load_dh_parameter_numbers (*numbers*)

Parameters **numbers** – A *DHParameterNumbers* instance.

Returns A new instance of *DHParameters*.

Raises *cryptography.exceptions.UnsupportedAlgorithm* – This is raised when any backend specific criteria are not met.

dh_parameters_supported (*p*, *g*, *q=None*)

Parameters

- **p** (*int*) – The p value of the DH key.
- **g** (*int*) – The g value of the DH key.
- **q** (*int*) – The q value of the DH key.

Returns True if the given values of p, g and q are supported by this backend, otherwise False.

New in version 1.8.

dh_x942_serialization_supported ()

Returns True if serialization of DH objects with subgroup order (q) is supported by this backend.

class *cryptography.hazmat.backends.interfaces.ScryptBackend*

New in version 1.6.

A backend with methods for using Scrypt.

The following backends implement this interface:

- *OpenSSL backend*

derive_script (*self*, *key_material*, *salt*, *length*, *n*, *r*, *p*)

Parameters

- **key_material** (*bytes*) – The key material to use as a basis for the derived key. This is typically a password.

- **salt** (*bytes*) – A salt.
- **length** (*int*) – The desired length of the derived key.
- **n** (*int*) – CPU/Memory cost parameter. It must be larger than 1 and be a power of 2.
- **r** (*int*) – Block size parameter.
- **p** (*int*) – Parallelization parameter.

Return bytes Derived key.

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

Bindings

`cryptography` aims to provide low-level CFFI based bindings to multiple native C libraries. These provide no automatic initialization of the library and may not provide complete wrappers for its API.

Using these functions directly is likely to require you to be careful in managing memory allocation, locking and other resources.

Individual bindings

This is a “Hazardous Materials” module. You should **ONLY** use it if you’re 100% absolutely sure that you know what you’re doing because this module is full of land mines, dragons, and dinosaurs with laser guns.

OpenSSL binding

These are CFFI bindings to the [OpenSSL C library](#). Cryptography supports OpenSSL version 1.0.1 and greater.

class `cryptography.hazmat.bindings.openssl.binding.Binding`

This is the exposed API for the OpenSSL bindings. It has two public attributes:

ffi

This is a `ffi.FFI` instance. It can be used to allocate and otherwise manipulate OpenSSL structures.

lib

This is a `ffi` library. It can be used to call OpenSSL functions, and access constants.

classmethod `init_static_locks()`

Enables the best available locking callback for OpenSSL. See [Threading](#).

Threading

`cryptography` enables OpenSSLs [thread safety facilities](#) in two different ways depending on the configuration of your system. Normally the locking callbacks provided by your Python implementation specifically for OpenSSL will be used. However, if you have linked `cryptography` to a different version of OpenSSL than that used by your Python implementation we enable an alternative locking callback. This version is implemented in Python and so may

result in lower performance in some situations. In particular parallelism is reduced because it has to acquire the GIL whenever any lock operations occur within OpenSSL.

Installation

You can install `cryptography` with `pip`:

```
$ pip install cryptography
```

Supported platforms

Currently we test `cryptography` on Python 2.6, 2.7, 3.3, 3.4, 3.5, 3.6, and PyPy 5.3+ on these operating systems.

- x86-64 CentOS 7.x
- x86-64 FreeBSD 11
- macOS 10.12 Sierra, 10.11 El Capitan, 10.10 Yosemite, 10.9 Mavericks
- x86-64 Ubuntu 14.04, 16.04, and rolling
- x86-64 Debian Wheezy (7.x), Jessie (8.x), Stretch (9.x), and Sid (unstable)
- 32-bit and 64-bit Python on 64-bit Windows Server 2012

Warning: Python 2.6 is no longer supported by the Python core team. A future version of `cryptography` will drop support for this version.

Python 3.3 support will be removed in the next `cryptography` release.

We test compiling with `clang` as well as `gcc` and use the following OpenSSL releases:

- OpenSSL 1.0.1
- OpenSSL 1.0.1e-fips (RHEL/CentOS 7)
- OpenSSL 1.0.1j-freebsd
- OpenSSL 1.0.1f
- OpenSSL 1.0.2-latest
- OpenSSL 1.1.0-latest

Building cryptography on Windows

The wheel package on Windows is a statically linked build (as of 0.5) so all dependencies are included. To install `cryptography`, you will typically just run

```
$ pip install cryptography
```

If you prefer to compile it yourself you'll need to have OpenSSL installed. You can compile OpenSSL yourself as well or use the binaries we build for our release infrastructure ([openssl-release](#)). Be sure to download the proper version for your architecture and Python (2010 works for Python 2.6, 2.7, 3.3, and 3.4 while 2015 is required for 3.5 and above). Wherever you place your copy of OpenSSL you'll need to set the `LIB` and `INCLUDE` environment variables to include the proper locations. For example:

```
C:\> \path\to\vcvarsall.bat x86_amd64
C:\> set LIB=C:\OpenSSL-win64\lib;%LIB%
C:\> set INCLUDE=C:\OpenSSL-win64\include;%INCLUDE%
C:\> pip install cryptography
```

As of OpenSSL 1.1.0 the library names have changed from `libeay32` and `ssleay32` to `libcrypto` and `libssl` (matching their names on all other platforms). `cryptography` links against the new 1.1.0 names by default. If you need to compile `cryptography` against an older version then you **must** set `CRYPTOGRAPHY_WINDOWS_LINK_LEGACY_OPENSSL` or else installation will fail.

If you need to rebuild `cryptography` for any reason be sure to clear the local `wheel` cache.

Building cryptography on Linux

`cryptography` should build very easily on Linux provided you have a C compiler, headers for Python (if you're not using `pyPy`), and headers for the OpenSSL and `libffi` libraries available on your system.

For Debian and Ubuntu, the following command will ensure that the required dependencies are installed (replace `python-dev` with `python3-dev` if you're using Python 3):

```
$ sudo apt-get install build-essential libssl-dev libffi-dev python-dev
```

For Fedora and RHEL-derivatives, the following command will ensure that the required dependencies are installed (replace `python-devel` with `python3-devel` if you're using Python 3):

```
$ sudo yum install gcc libffi-devel python-devel openssl-devel
```

You should now be able to build and install `cryptography` with the usual

```
$ pip install cryptography
```

Using your own OpenSSL on Linux

Python links to OpenSSL for its own purposes and this can sometimes cause problems when you wish to use a different version of OpenSSL with `cryptography`. If you want to use `cryptography` with your own build of OpenSSL you will need to make sure that the build is configured correctly so that your version of OpenSSL doesn't conflict with Python's.

The options you need to add allow the linker to identify every symbol correctly even when multiple versions of the library are linked into the same program. If you are using your distribution's source packages these will probably be patched in for you already, otherwise you'll need to use options something like this when configuring OpenSSL:

```
$ ./config -Wl,--version-script=openssl.ld -Wl,-Bsymbolic-functions -fPIC shared
```

You'll also need to generate your own `openssl.ld` file. For example:

```
OPENSSL_1.1.0E_CUSTOM {
    global:
        *;
};
```

You should replace the version string on the first line as appropriate for your build.

Static Wheels

Cryptography ships statically-linked wheels for macOS and Windows, ensuring that these platforms can always use the most-recent OpenSSL, regardless of what is shipped by default on those platforms. As a result of various difficulties around Linux binary linking, Cryptography cannot do the same on Linux.

However, you can build your own statically-linked wheels that will work on your own systems. This will allow you to continue to use relatively old Linux distributions (such as LTS releases), while making sure you have the most recent OpenSSL available to your Python programs.

To do so, you should find yourself a machine that is as similar as possible to your target environment (e.g. your production environment): for example, spin up a new cloud server running your target Linux distribution. On this machine, install the Cryptography dependencies as mentioned in *Building cryptography on Linux*. Please also make sure you have `virtualenv` installed: this should be available from your system package manager.

Then, paste the following into a shell script. You'll need to populate the `OPENSSL_VERSION` variable. To do that, visit [openssl.org](https://www.openssl.org) and find the latest non-FIPS release version number, then set the string appropriately. For example, for OpenSSL 1.0.2k, use `OPENSSL_VERSION="1.0.2k"`.

When this shell script is complete, you'll find a collection of wheel files in a directory called `wheelhouse`. These wheels can be installed by a sufficiently-recent version of `pip`. The Cryptography wheel in this directory contains a statically-linked OpenSSL binding, which ensures that you have access to the most-recent OpenSSL releases without corrupting your system dependencies.

```
set -e

OPENSSL_VERSION="VERSIONGOESHERE"
CWD=$(pwd)

virtualenv env
. env/bin/activate
pip install -U setuptools
pip install -U wheel pip
curl -O https://www.openssl.org/source/openssl-${OPENSSL_VERSION}.tar.gz
tar xvf openssl-${OPENSSL_VERSION}.tar.gz
cd openssl-${OPENSSL_VERSION}
./config no-shared no-ssl2 no-ssl3 -fPIC --prefix=${CWD}/openssl
make && make install
cd ..
CFLAGS="-I${CWD}/openssl/include" LDFLAGS="-L${CWD}/openssl/lib" pip wheel --no-use-
↪wheel cryptography
```

Building cryptography on macOS

Note: If installation gives a fatal error: `'openssl/aes.h' file not found` see the [FAQ](#) for information about how to fix this issue.

The wheel package on macOS is a statically linked build (as of 1.0.1) so for users with `pip` 8 or above you only need one step:

```
$ pip install cryptography
```

If you want to build cryptography yourself or are on an older macOS version, cryptography requires the presence of a C compiler, development headers, and the proper libraries. On macOS much of this is provided by Apple's Xcode development tools. To install the Xcode command line tools (on macOS 10.9+) open a terminal window and run:

```
$ xcode-select --install
```

This will install a compiler (clang) along with (most of) the required development headers.

You'll also need OpenSSL, which you can obtain from [Homebrew](#) or [MacPorts](#). Cryptography does **not** support Apple's deprecated OpenSSL distribution.

To build cryptography and dynamically link it:

Homebrew

```
$ brew install openssl@1.1
$ env LDFLAGS="-L$(brew --prefix openssl@1.1)/lib" CFLAGS="-I$(brew --prefix_
↳openssl@1.1)/include" pip install cryptography
```

MacPorts:

```
$ sudo port install openssl
$ env LDFLAGS="-L/opt/local/lib" CFLAGS="-I/opt/local/include" pip install_
↳cryptography
```

You can also build cryptography statically:

Homebrew

```
$ brew install openssl@1.1
$ env CRYPTOGRAPHY_SUPPRESS_LINK_FLAGS=1 LDFLAGS="$(brew --prefix openssl@1.1)/lib/
↳libssl.a $(brew --prefix openssl@1.1)/lib/libcrypto.a" CFLAGS="-I$(brew --prefix_
↳openssl@1.1)/include" pip install cryptography
```

MacPorts:

```
$ sudo port install openssl
$ env CRYPTOGRAPHY_SUPPRESS_LINK_FLAGS=1 LDFLAGS="/opt/local/lib/libssl.a /opt/local/
↳lib/libcrypto.a" CFLAGS="-I/opt/local/include" pip install cryptography
```

If you need to rebuild cryptography for any reason be sure to clear the local `wheel cache`.

Building cryptography with conda

Because of a bug in conda, attempting to install cryptography out of the box will result in an error. This can be resolved by setting the library path environment variable for your platform.

On macOS:

```
$ env DYLD_LIBRARY_PATH="$HOME/anaconda/lib" pip install cryptography
```

and on Linux:

```
$ env LD_LIBRARY_PATH="$HOME/anaconda/lib" pip install cryptography
```

You will need to set this variable every time you start Python. For more information, consult [Greg Wilson's blog post](#) on the subject.

Changelog

2.0 - master

Note: This version is not yet released and is under active development.

- Deprecated the use of `signer` on `RSAPrivateKey`, `DSAPrivateKey`, and `EllipticCurvePrivateKey` in favor of `sign`.
- Deprecated the use of `verifier` on `RSAPublicKey`, `DSAPublicKey`, and `EllipticCurvePublicKey` in favor of `verify`.
- Added support for parsing `SignedCertificateTimestamp` objects from X.509 certificate extensions.
- Added support for `ChaCha20Poly1305`.
- Added support for `X25519` key exchange.

1.9 - 2017-05-29

- **BACKWARDS INCOMPATIBLE:** Elliptic Curve signature verification no longer returns `True` on success. This brings it in line with the interface's documentation, and our intent. The correct way to use `verify()` has always been to check whether or not `InvalidSignature` was raised.
- **BACKWARDS INCOMPATIBLE:** Dropped support for macOS 10.7 and 10.8.
- **BACKWARDS INCOMPATIBLE:** The minimum supported PyPy version is now 5.3.
- Python 3.3 support has been deprecated, and will be removed in the next cryptography release.
- Add support for providing `tag` during `GCM` finalization via `finalize_with_tag()`.
- Fixed an issue preventing `cryptography` from compiling against LibreSSL 2.5.x.
- Added `key_size()` and `key_size()` as convenience methods for determining the bit size of a secret scalar for the curve.
- Accessing an unrecognized extension marked critical on an X.509 object will no longer raise an `UnsupportedExtension` exception, instead an `UnrecognizedExtension` object will be returned. This behavior was based on a poor reading of the RFC, unknown critical extensions only need to be rejected on certificate verification.
- The `CommonCrypto` backend has been removed.
- `MultiBackend` has been removed.
- `Whirlpool` and `RIPEMD160` have been deprecated.

1.8.2 - 2017-05-26

- Fixed a compilation bug affecting OpenSSL 1.1.0f.
- Updated Windows and macOS wheels to be compiled against OpenSSL 1.1.0f.

1.8.1 - 2017-03-10

- Fixed macOS wheels to properly link against 1.1.0 rather than 1.0.2.

1.8 - 2017-03-09

- Added support for Python 3.6.
- Windows and macOS wheels now link against OpenSSL 1.1.0.
- macOS wheels are no longer universal. This change significantly shrinks the size of the wheels. Users on macOS 32-bit Python (if there are any) should migrate to 64-bit or build their own packages.
- Changed ASN.1 dependency from `pyasn1` to `asn1crypto` resulting in a general performance increase when encoding/decoding ASN.1 structures. Also, the `pyasn1_modules` test dependency is no longer required.
- Added support for `update_into()` on `CipherContext`.
- Added `private_bytes()` to `DHPrivateKeyWithSerialization`.
- Added `public_bytes()` to `DHPublicKeyWithSerialization`.
- `load_pem_private_key()` and `load_der_private_key()` now require that password must be bytes if provided. Previously this was documented but not enforced.
- Added support for subgroup order in *Diffie-Hellman key exchange*.

1.7.2 - 2017-01-27

- Updated Windows and macOS wheels to be compiled against OpenSSL 1.0.2k.

1.7.1 - 2016-12-13

- Fixed a regression in `int_from_bytes` where it failed to accept `bytearray`.

1.7 - 2016-12-12

- Support for OpenSSL 1.0.0 has been removed. Users on older version of OpenSSL will need to upgrade.
- Added support for Diffie-Hellman key exchange using `exchange()`.
- The OS random engine for OpenSSL has been rewritten to improve compatibility with embedded Python and other edge cases. More information about this change can be found in the [pull request](#).

1.6 - 2016-11-22

- Deprecated support for OpenSSL 1.0.0. Support will be removed in `cryptography 1.7`.
- Replaced the Python-based OpenSSL locking callbacks with a C version to fix a potential deadlock that could occur if a garbage collection cycle occurred while inside the lock.
- Added support for `BLAKE2b` and `BLAKE2s` when using OpenSSL 1.1.0.
- Added `signature_algorithm_oid` support to `Certificate`.
- Added `signature_algorithm_oid` support to `CertificateSigningRequest`.

- Added `signature_algorithm_oid` support to `CertificateRevocationList`.
- Added support for `Scrypt` when using OpenSSL 1.1.0.
- Added a workaround to improve compatibility with Python application bundling tools like PyInstaller and `cx_freeze`.
- Added support for generating a `random_serial_number()`.
- Added support for encoding `IPv4Network` and `IPv6Network` in X.509 certificates for use with `NameConstraints`.
- Added `public_bytes()` to `Name`.
- Added `RelativeDistinguishedName`
- `DistributionPoint` now accepts `RelativeDistinguishedName` for `relative_name`. Depreciated use of `Name` as `relative_name`.
- `Name` now accepts an iterable of `RelativeDistinguishedName`. RDNs can be accessed via the `rdns` attribute. When constructed with an iterable of `NameAttribute`, each attribute becomes a single-valued RDN.
- Added `derive_private_key()`.
- Added support for signing and verifying RSA, DSA, and ECDSA signatures with `Prehashed` digests.

1.5.3 - 2016-11-05

- **SECURITY ISSUE:** Fixed a bug where HKDF would return an empty byte-string if used with a length less than `algorithm.digest_size`. Credit to **Markus Döring** for reporting the issue. *CVE-2016-9243*

1.5.2 - 2016-09-26

- Updated Windows and OS X wheels to be compiled against OpenSSL 1.0.2j.

1.5.1 - 2016-09-22

- Updated Windows and OS X wheels to be compiled against OpenSSL 1.0.2i.
- Resolved a `UserWarning` when used with `ffi` 1.8.3.
- Fixed a memory leak in name creation with X.509.
- Added a workaround for old versions of `setuptools`.
- Fixed an issue preventing `cryptography` from compiling against OpenSSL 1.0.2i.

1.5 - 2016-08-26

- Added `calculate_max_pss_salt_length()`.
- Added “one shot” `sign()` and `verify()` methods to DSA keys.
- Added “one shot” `sign()` and `verify()` methods to ECDSA keys.
- Switched back to the older callback model on Python 3.5 in order to mitigate the locking callback problem with OpenSSL <1.1.0.

- *CertificateBuilder*, *CertificateRevocationListBuilder*, and *RevokedCertificateBuilder* now accept timezone aware datetime objects as method arguments
- cryptography now supports OpenSSL 1.1.0 as a compilation target.

1.4 - 2016-06-04

- Support for OpenSSL 0.9.8 has been removed. Users on older versions of OpenSSL will need to upgrade.
- Added *KBKDFHMAC*.
- Added support for OpenSSH public key serialization.
- Added support for SHA-2 in RSA *OAEP* when using OpenSSL 1.0.2 or greater.
- Added “one shot” *sign()* and *verify()* methods to RSA keys.
- Deprecated the *serial* attribute on *Certificate*, in favor of *serial_number*.

1.3.4 - 2016-06-03

- Added another OpenSSL function to the bindings to support an upcoming pyOpenSSL release.

1.3.3 - 2016-06-02

- Added two new OpenSSL functions to the bindings to support an upcoming pyOpenSSL release.

1.3.2 - 2016-05-04

- Updated Windows and OS X wheels to be compiled against OpenSSL 1.0.2h.
- Fixed an issue preventing cryptography from compiling against LibreSSL 2.3.x.

1.3.1 - 2016-03-21

- Fixed a bug that caused an *AttributeError* when using *mock* to patch some cryptography modules.

1.3 - 2016-03-18

- Added support for padding ANSI X.923 with *ANSIX923*.
- Deprecated support for OpenSSL 0.9.8. Support will be removed in cryptography 1.4.
- Added support for the *PolicyConstraints* X.509 extension including both parsing and generation using *CertificateBuilder* and *CertificateSigningRequestBuilder*.
- Added *is_signature_valid* to *CertificateSigningRequest*.
- Fixed an intermittent *AssertionError* when performing an RSA decryption on an invalid ciphertext, *ValueError* is now correctly raised in all cases.
- Added *from_issuer_subject_key_identifier()*.

1.2.3 - 2016-03-01

- Updated Windows and OS X wheels to be compiled against OpenSSL 1.0.2g.

1.2.2 - 2016-01-29

- Updated Windows and OS X wheels to be compiled against OpenSSL 1.0.2f.

1.2.1 - 2016-01-08

- Reverts a change to an OpenSSL `EVP_PKEY` object that caused errors with `pyOpenSSL`.

1.2 - 2016-01-08

- **BACKWARDS INCOMPATIBLE:** `RevokedCertificate` `extensions` now uses extension classes rather than returning raw values inside the `Extension` `value`. The new classes are:
 - `CertificateIssuer`
 - `CRLReason`
 - `InvalidityDate`
- Deprecated support for OpenSSL 0.9.8 and 1.0.0. At this time there is no time table for actually dropping support, however we strongly encourage all users to upgrade, as those versions no longer receive support from the OpenSSL project.
- The `Certificate` class now has `signature` and `tbs_certificate_bytes` attributes.
- The `CertificateSigningRequest` class now has `signature` and `tbs_certrequest_bytes` attributes.
- The `CertificateRevocationList` class now has `signature` and `tbs_certlist_bytes` attributes.
- `NameConstraints` are now supported in the `CertificateBuilder` and `CertificateSigningRequestBuilder`.
- Support serialization of certificate revocation lists using the `public_bytes()` method of `CertificateRevocationList`.
- Add support for parsing `CertificateRevocationList` `extensions()` in the OpenSSL backend. The following extensions are currently supported:
 - `AuthorityInformationAccess`
 - `AuthorityKeyIdentifier`
 - `CRLNumber`
 - `IssuerAlternativeName`
- Added `CertificateRevocationListBuilder` and `RevokedCertificateBuilder` to allow creation of CRLs.
- Unrecognized non-critical X.509 extensions are now parsed into an `UnrecognizedExtension` object.

1.1.2 - 2015-12-10

- Fixed a SIGBUS crash with the OS X wheels caused by redefinition of a method.
- Fixed a runtime error `undefined symbol EC_GFp_nistp224_method` that occurred with some OpenSSL installations.
- Updated Windows and OS X wheels to be compiled against OpenSSL 1.0.2e.

1.1.1 - 2015-11-19

- Fixed several small bugs related to compiling the OpenSSL bindings with unusual OpenSSL configurations.
- Resolved an issue where, depending on the method of installation and which Python interpreter they were using, users on El Capitan (OS X 10.11) may have seen an `InternalError` on import.

1.1 - 2015-10-28

- Added support for Elliptic Curve Diffie-Hellman with *ECDH*.
- Added *X963KDF*.
- Added support for parsing certificate revocation lists (CRLs) using *load_pem_x509_crl()* and *load_der_x509_crl()*.
- Add support for AES key wrapping with *aes_key_wrap()* and *aes_key_unwrap()*.
- Added a `__hash__` method to *Name*.
- Add support for encoding and decoding elliptic curve points to a byte string form using *encode_point()* and *from_encoded_point()*.
- Added *get_extension_for_class()*.
- *CertificatePolicies* are now supported in the *CertificateBuilder*.
- `countryName` is now encoded as a `PrintableString` when creating subject and issuer distinguished names with the *Certificate* and *CSR* builder classes.

1.0.2 - 2015-09-27

- **SECURITY ISSUE:** The OpenSSL backend prior to 1.0.2 made extensive use of assertions to check response codes where our tests could not trigger a failure. However, when Python is run with `-O` these asserts are optimized away. If a user ran Python with this flag and got an invalid response code this could result in undefined behavior or worse. Accordingly, all response checks from the OpenSSL backend have been converted from `assert` to a true function call. Credit **Emilia Käsper (Google Security Team)** for the report.

1.0.1 - 2015-09-05

- We now ship OS X wheels that statically link OpenSSL by default. When installing a wheel on OS X 10.10+ (and using a Python compiled against the 10.10 SDK) users will no longer need to compile. See *Installation* for alternate installation methods if required.
- Set the default string mask to UTF-8 in the OpenSSL backend to resolve character encoding issues with older versions of OpenSSL.
- Several new OpenSSL bindings have been added to support a future pyOpenSSL release.

- Raise an error during install on PyPy < 2.6. 1.0+ requires PyPy 2.6+.

1.0 - 2015-08-12

- Switched to the new `ffi set_source` out-of-line API mode for compilation. This results in significantly faster imports and lowered memory consumption. Due to this change we no longer support PyPy releases older than 2.6 nor do we support any released version of PyPy3 (until a version supporting `ffi 1.0` comes out).
- Fix parsing of OpenSSH public keys that have spaces in comments.
- Support serialization of certificate signing requests using the `public_bytes` method of `CertificateSigningRequest`.
- Support serialization of certificates using the `public_bytes` method of `Certificate`.
- Add `get_provisioning_uri` method to `HOTP` and `TOTP` for generating provisioning URIs.
- Add `ConcatKDFHash` and `ConcatKDFHMAC`.
- Raise a `TypeError` when passing objects that are not text as the value to `NameAttribute`.
- Add support for `OtherName` as a general name type.
- Added new X.509 extension support in `Certificate` The following new extensions are now supported:
 - `OCSPNoCheck`
 - `InhibitAnyPolicy`
 - `IssuerAlternativeName`
 - `NameConstraints`
- Extension support was added to `CertificateSigningRequest`.
- Add support for creating signed certificates with `CertificateBuilder`. This includes support for the following extensions:
 - `BasicConstraints`
 - `SubjectAlternativeName`
 - `KeyUsage`
 - `ExtendedKeyUsage`
 - `SubjectKeyIdentifier`
 - `AuthorityKeyIdentifier`
 - `AuthorityInformationAccess`
 - `CRLDistributionPoints`
 - `InhibitAnyPolicy`
 - `IssuerAlternativeName`
 - `OCSPNoCheck`
- Add support for creating certificate signing requests with `CertificateSigningRequestBuilder`. This includes support for the same extensions supported in the `CertificateBuilder`.
- Deprecate `encode_rfc6979_signature` and `decode_rfc6979_signature` in favor of `encode_dss_signature()` and `decode_dss_signature()`.

0.9.3 - 2015-07-09

- Updated Windows wheels to be compiled against OpenSSL 1.0.2d.

0.9.2 - 2015-07-04

- Updated Windows wheels to be compiled against OpenSSL 1.0.2c.

0.9.1 - 2015-06-06

- **SECURITY ISSUE:** Fixed a double free in the OpenSSL backend when using DSA to verify signatures. Note that this only affects PyPy 2.6.0 and (presently unreleased) CFFI versions greater than 1.1.0.

0.9 - 2015-05-13

- Removed support for Python 3.2. This version of Python is rarely used and caused support headaches. Users affected by this should upgrade to 3.3+.
- Deprecated support for Python 2.6. At the time there is no time table for actually dropping support, however we strongly encourage all users to upgrade their Python, as Python 2.6 no longer receives support from the Python core team.
- Add support for the *SECP256K1* elliptic curve.
- Fixed compilation when using an OpenSSL which was compiled with the `no-comp` (`OPENSSL_NO_COMP`) option.
- Support *DER* serialization of public keys using the `public_bytes` method of *RSAPublicKeyWithSerialization*, *DSAPublicKeyWithSerialization*, and *EllipticCurvePublicKeyWithSerialization*.
- Support *DER* serialization of private keys using the `private_bytes` method of *RSAPrivateKeyWithSerialization*, *DSAPrivateKeyWithSerialization*, and *EllipticCurvePrivateKeyWithSerialization*.
- Add support for parsing X.509 certificate signing requests (CSRs) with `load_pem_x509_csr()` and `load_der_x509_csr()`.
- Moved `cryptology.exceptions.InvalidToken` to `cryptology.hazmat.primitives.twofactor.InvalidToken` and deprecated the old location. This was moved to minimize confusion between this exception and `cryptology.fernet.InvalidToken`.
- Added support for X.509 extensions in *Certificate* objects. The following extensions are supported as of this release:
 - *BasicConstraints*
 - *AuthorityKeyIdentifier*
 - *SubjectKeyIdentifier*
 - *KeyUsage*
 - *SubjectAlternativeName*
 - *ExtendedKeyUsage*
 - *CRLDistributionPoints*

- *AuthorityInformationAccess*
- *CertificatePolicies*

Note that unsupported extensions with the critical flag raise `UnsupportedExtension` while unsupported extensions set to non-critical are silently ignored. Read the *X.509 documentation* for more information.

0.8.2 - 2015-04-10

- Fixed a race condition when initializing the OpenSSL or CommonCrypto backends in a multi-threaded scenario.

0.8.1 - 2015-03-20

- Updated Windows wheels to be compiled against OpenSSL 1.0.2a.

0.8 - 2015-03-08

- *load_ssh_public_key()* can now load elliptic curve public keys.
- Added *signature_hash_algorithm* support to *Certificate*.
- Added *rsa_recover_prime_factors()*
- *KeyDerivationFunction* was moved from `cryptography.hazmat.primitives.interfaces` to *kdf*.
- Added support for parsing X.509 names. See the *X.509 documentation* for more information.
- Added *load_der_private_key()* to support loading of DER encoded private keys and *load_der_public_key()* to support loading DER encoded public keys.
- Fixed building against LibreSSL, a compile-time substitute for OpenSSL.
- FreeBSD 9.2 was removed from the continuous integration system.
- Updated Windows wheels to be compiled against OpenSSL 1.0.2.
- *load_pem_public_key()* and *load_der_public_key()* now support PKCS1 RSA public keys (in addition to the previous support for SubjectPublicKeyInfo format for RSA, EC, and DSA).
- Added *EllipticCurvePrivateKeyWithSerialization* and deprecated *EllipticCurvePrivateKeyWithNumbers*.
- Added *private_bytes()* to *EllipticCurvePrivateKeyWithSerialization*.
- Added *RSAPrivateKeyWithSerialization* and deprecated *RSAPrivateKeyWithNumbers*.
- Added *private_bytes()* to *RSAPrivateKeyWithSerialization*.
- Added *DSAPrivateKeyWithSerialization* and deprecated *DSAPrivateKeyWithNumbers*.
- Added *private_bytes()* to *DSAPrivateKeyWithSerialization*.
- Added *RSAPublicKeyWithSerialization* and deprecated *RSAPublicKeyWithNumbers*.
- Added *public_bytes* to *RSAPublicKeyWithSerialization*.
- Added *EllipticCurvePublicKeyWithSerialization* and deprecated *EllipticCurvePublicKeyWithNumbers*.
- Added *public_bytes* to *EllipticCurvePublicKeyWithSerialization*.

- Added *DSAPublicKeyWithSerialization* and deprecated *DSAPublicKeyWithNumbers*.
- Added *public_bytes* to *DSAPublicKeyWithSerialization*.
- *HashAlgorithm* and *HashContext* were moved from `cryptography.hazmat.primitives.interfaces` to *hashes*.
- *CipherContext*, *AEADCipherContext*, *AEADEncryptionContext*, *CipherAlgorithm*, and *BlockCipherAlgorithm* were moved from `cryptography.hazmat.primitives.interfaces` to *ciphers*.
- *Mode*, *ModeWithInitializationVector*, *ModeWithNonce*, and *ModeWithAuthenticationTag* were moved from `cryptography.hazmat.primitives.interfaces` to *modes*.
- *PaddingContext* was moved from `cryptography.hazmat.primitives.interfaces` to *padding*.
- *AsymmetricPadding* was moved from `cryptography.hazmat.primitives.interfaces` to *padding*.
- *AsymmetricSignatureContext* and *AsymmetricVerificationContext* were moved from `cryptography.hazmat.primitives.interfaces` to `cryptography.hazmat.primitives.asymmetric`.
- *DSAParameters*, *DSAParametersWithNumbers*, *DSAPrivateKey*, *DSAPrivateKeyWithNumbers*, *DSAPublicKey* and *DSAPublicKeyWithNumbers* were moved from `cryptography.hazmat.primitives.interfaces` to *dsa*.
- *EllipticCurve*, *EllipticCurveSignatureAlgorithm*, *EllipticCurvePrivateKey*, *EllipticCurvePrivateKeyWithNumbers*, *EllipticCurvePublicKey*, and *EllipticCurvePublicKeyWithNumbers* were moved from `cryptography.hazmat.primitives.interfaces` to *ec*.
- *RSAPrivateKey*, *RSAPrivateKeyWithNumbers*, *RSAPublicKey* and *RSAPublicKeyWithNumbers* were moved from `cryptography.hazmat.primitives.interfaces` to *rsa*.

0.7.2 - 2015-01-16

- Updated Windows wheels to be compiled against OpenSSL 1.0.11.
- `enum34` is no longer installed on Python 3.4, where it is included in the standard library.
- Added a new function to the OpenSSL bindings to support additional functionality in `pyOpenSSL`.

0.7.1 - 2014-12-28

- Fixed an issue preventing compilation on platforms where `OPENSSL_NO_SSL3` was defined.

0.7 - 2014-12-17

- Cryptography has been relicensed from the Apache Software License, Version 2.0, to being available under *either* the Apache Software License, Version 2.0, or the BSD license.
- Added key-rotation support to *Fernet* with *MultiFernet*.
- More bit-lengths are now supported for *p* and *q* when loading DSA keys from numbers.

- Added `MACContext` as a common interface for CMAC and HMAC and deprecated `CMACContext`.
- Added support for encoding and decoding **RFC 6979** signatures in *Asymmetric Utilities*.
- Added `load_ssh_public_key()` to support the loading of OpenSSH public keys (**RFC 4253**). Only RSA and DSA keys are currently supported.
- Added initial support for X.509 certificate parsing. See the *X.509 documentation* for more information.

0.6.1 - 2014-10-15

- Updated Windows wheels to be compiled against OpenSSL 1.0.1j.
- Fixed an issue where OpenSSL 1.0.1j changed the errors returned by some functions.
- Added our license file to the `cryptography-vectors` package.
- Implemented DSA hash truncation support (per FIPS 186-3) in the OpenSSL backend. This works around an issue in 1.0.0, 1.0.0a, and 1.0.0b where truncation was not implemented.

0.6 - 2014-09-29

- Added `load_pem_private_key()` to ease loading private keys, and `load_pem_public_key()` to support loading public keys.
- Removed the, deprecated in 0.4, support for the `salt_length` argument to the `MGF1` constructor. The `salt_length` should be passed to `PSS` instead.
- Fix compilation on OS X Yosemite.
- Deprecated `elliptic_curve_private_key_from_numbers` and `elliptic_curve_public_key_from_numbers` in favor of `load_elliptic_curve_private_numbers` and `load_elliptic_curve_public_numbers` on *EllipticCurveBackend*.
- Added `EllipticCurvePrivateKeyWithNumbers` and `EllipticCurvePublicKeyWithNumbers` support.
- Work around three GCM related bugs in CommonCrypto and OpenSSL.
 - On the CommonCrypto backend adding AAD but not subsequently calling update would return null tag bytes.
 - On the CommonCrypto backend a call to update without an empty add AAD call would return null ciphertext bytes.
 - On the OpenSSL backend with certain versions adding AAD only would give invalid tag bytes.
- Support loading EC private keys from PEM.

0.5.4 - 2014-08-20

- Added several functions to the OpenSSL bindings to support new functionality in pyOpenSSL.
- Fixed a redefined constant causing compilation failure with Solaris 11.2.

0.5.3 - 2014-08-06

- Updated Windows wheels to be compiled against OpenSSL 1.0.1i.

0.5.2 - 2014-07-09

- Add `TraditionalOpenSSLSerializationBackend` support to `multibackend`.
- Fix compilation error on OS X 10.8 (Mountain Lion).

0.5.1 - 2014-07-07

- Add `PKCS8SerializationBackend` support to `multibackend`.

0.5 - 2014-07-07

- **BACKWARDS INCOMPATIBLE:** `GCM` no longer allows truncation of tags by default. Previous versions of `cryptography` allowed tags to be truncated by default, applications wishing to preserve this behavior (not recommended) can pass the `min_tag_length` argument.
- Windows builds now statically link OpenSSL by default. When installing a wheel on Windows you no longer need to install OpenSSL separately. Windows users can switch between static and dynamic linking with an environment variable. See *Installation* for more details.
- Added `HKDFExpand`.
- Added `CFB8` support for `AES` and `TripleDES` on `commoncrypto` and `OpenSSL backend`.
- Added `AES CTR` support to the OpenSSL backend when linked against 0.9.8.
- Added `PKCS8SerializationBackend` and `TraditionalOpenSSLSerializationBackend` support to the `OpenSSL backend`.
- Added `Elliptic curve cryptography` and `EllipticCurveBackend`.
- Added `ECB` support for `TripleDES` on `commoncrypto` and `OpenSSL backend`.
- Deprecated the concrete `RSAPrivateKey` class in favor of backend specific providers of the `cryptography.hazmat.primitives.asymmetric.rsa.RSAPrivateKey` interface.
- Deprecated the concrete `RSAPublicKey` in favor of backend specific providers of the `cryptography.hazmat.primitives.asymmetric.rsa.RSAPublicKey` interface.
- Deprecated the concrete `DSAPrivateKey` class in favor of backend specific providers of the `cryptography.hazmat.primitives.asymmetric.dsa.DSAPrivateKey` interface.
- Deprecated the concrete `DSAPublicKey` class in favor of backend specific providers of the `cryptography.hazmat.primitives.asymmetric.dsa.DSAPublicKey` interface.
- Deprecated the concrete `DSAParameters` class in favor of backend specific providers of the `cryptography.hazmat.primitives.asymmetric.dsa.DSAParameters` interface.
- Deprecated `encrypt_rsa`, `decrypt_rsa`, `create_rsa_signature_ctx` and `create_rsa_verification_ctx` on `RSABackend`.
- Deprecated `create_dsa_signature_ctx` and `create_dsa_verification_ctx` on `DSABackend`.

0.4 - 2014-05-03

- Deprecated `salt_length` on `MGF1` and added it to `PSS`. It will be removed from `MGF1` in two releases per our *API stability* policy.

- Added *SEED* support.
- Added *CMAC*.
- Added decryption support to *RSAPrivateKey* and encryption support to *RSAPublicKey*.
- Added signature support to *DSAPrivateKey* and verification support to *DSAPublicKey*.

0.3 - 2014-03-27

- Added *HOTP*.
- Added *TOTP*.
- Added *IDEA* support.
- Added signature support to *RSAPrivateKey* and verification support to *RSAPublicKey*.
- Moved test vectors to the new `cryptography_vectors` package.

0.2.2 - 2014-03-03

- Removed a constant definition that was causing compilation problems with specific versions of OpenSSL.

0.2.1 - 2014-02-22

- Fix a bug where importing cryptography from multiple paths could cause initialization to fail.

0.2 - 2014-02-20

- Added `commoncrypto`.
- Added initial `commoncrypto`.
- Removed `register_cipher_adapter` method from *CipherBackend*.
- Added support for the OpenSSL backend under Windows.
- Improved thread-safety for the OpenSSL backend.
- Fixed compilation on systems where OpenSSL's `ec.h` header is not available, such as CentOS.
- Added *PBKDF2HMAC*.
- Added *HKDF*.
- Added `multibackend`.
- Set default random for the *OpenSSL backend* to the OS random engine.
- Added *CAST5* (CAST-128) support.

0.1 - 2014-01-08

- Initial release.

Frequently asked questions

cryptography failed to install!

If you are having issues installing `cryptography` the first troubleshooting step is to upgrade `pip` and then try to install again. For most users this will take the form of `pip install -U pip`, but on Windows you should do `python -m pip install -U pip`. If you are still seeing errors after upgrading and trying `pip install cryptography` again, please see the *Installation* documentation.

How does cryptography compare to NaCl (Networking and Cryptography Library)?

While `cryptography` and `NaCl` both share the goal of making cryptography easier, and safer, to use for developers, `cryptography` is designed to be a general purpose library, interoperable with existing systems, while `NaCl` features a collection of hand selected algorithms.

`cryptography`'s *recipes* layer has similar goals to `NaCl`.

If you prefer `NaCl`'s design, we highly recommend `PyNaCl`.

Why use cryptography?

If you've done cryptographic work in Python before you have likely encountered other libraries in Python such as `M2Crypto`, `PyCrypto`, or `PyOpenSSL`. In building `cryptography` we wanted to address a few issues we observed in the legacy libraries:

- Extremely error prone APIs and insecure defaults.
- Use of poor implementations of algorithms (i.e. ones with known side-channel attacks).
- Lack of maintenance.
- Lack of high level APIs.
- Lack of PyPy and Python 3 support.
- Absence of algorithms such as `AES-GCM` and `HKDF`.

Compiling cryptography on macOS produces a fatal error: 'openssl/aes.h' file not found error

This happens because macOS 10.11 no longer includes a copy of OpenSSL. `cryptography` now provides wheels which include a statically linked copy of OpenSSL. You're seeing this error because your copy of `pip` is too old to find our wheel files. Upgrade your copy of `pip` with `pip install -U pip` and then try install `cryptography` again.

If you are using PyPy, we do not currently ship `cryptography` wheels for PyPy. You will need to install your own copy of OpenSSL – we recommend using Homebrew.

Starting cryptography using mod_wsgi produces an InternalError during a call in _register_osrandom_engine

Upgrade to the latest `cryptography` and this issue should be resolved.

cryptography raised an `InternalError` and I'm not sure what to do?

Frequently `InternalError` is raised when there are errors on the OpenSSL error stack that were placed there by other libraries that are also using OpenSSL. Try removing the other libraries and see if the problem persists. If you have no other libraries using OpenSSL in your process, or they do not appear to be at fault, it's possible that this is a bug in `cryptography`. Please file an [issue](#) with instructions on how to reproduce it.

Installing `cryptography` fails with `ImportError: No module named setuptools_ext`

Your `ffi` package is out of date. `pip install -U ffi` to update it.

Installing `cryptography` with OpenSSL 0.9.8 or 1.0.0 fails

The OpenSSL project has dropped support for the 0.9.8 and 1.0.0 release series. Since they are no longer receiving security patches from upstream, `cryptography` is also dropping support for them. To fix this issue you should upgrade to a newer version of OpenSSL (1.0.1 or later). This may require you to upgrade to a newer operating system.

Development

As an open source project, `cryptography` welcomes contributions of all forms. The sections below will help you get started.

File bugs and feature requests on our issue tracker on [GitHub](#). If it is a bug check out [what to put in your bug report](#).

Getting started

Development dependencies

Working on `cryptography` requires the installation of a small number of development dependencies in addition to the dependencies for *Installation*. These are listed in `dev-requirements.txt` and they can be installed in a `virtualenv` using `pip`. Before you install them, follow the **build** instructions in *Installation* (be sure to stop before actually installing `cryptography`). Once you've done that, install the development dependencies, and then install `cryptography` in `editable` mode. For example:

```
$ # Create a virtualenv and activate it
$ # Set up your cryptography build environment
$ pip install --requirement dev-requirements.txt
$ pip install --editable .
```

You will also need to install `enchant` using your system's package manager to check spelling in the documentation.

Note: There is an upstream bug in `enchant` that prevents its installation on Windows with 64-bit Python. See [this Github issue](#) for more information. The easiest workaround is to use 32-bit Python for `cryptography` development, even on 64-bit Windows.

You are now ready to run the tests and build the documentation.

OpenSSL on macOS

You must have installed [OpenSSL](#) via [Homebrew](#) or [MacPorts](#) and must set `CFLAGS` and `LDFLAGS` environment variables before installing the `dev-requirements.txt` otherwise pip will fail with include errors.

For example, with [Homebrew](#):

```
$ env LDFLAGS="-L$(brew --prefix openssl@1.1)/lib" \  
    CFLAGS="-I$(brew --prefix openssl@1.1)/include" \  
    pip install --requirement ./dev-requirements.txt
```

Alternatively for a static build you can specify `CRYPTOGRAPHY_SUPPRESS_LINK_FLAGS=1` and ensure `LDFLAGS` points to the absolute path for the [OpenSSL](#) libraries before calling pip.

Tip: You will also need to set these values when *Building documentation*.

Running tests

`cryptography` unit tests are found in the `tests/` directory and are designed to be run using `pytest`. `pytest` will discover the tests automatically, so all you have to do is:

```
$ py.test  
...  
62746 passed in 220.43 seconds
```

This runs the tests with the default Python interpreter.

You can also verify that the tests pass on other supported Python interpreters. For this we use `tox`, which will automatically create a [virtualenv](#) for each supported Python version and run the tests. For example:

```
$ tox  
...  
ERROR: py26: InterpreterNotFound: python2.6  
py27: commands succeeded  
ERROR: pypy: InterpreterNotFound: pypy  
py33: commands succeeded  
docs: commands succeeded  
pep8: commands succeeded
```

You may not have all the required Python versions installed, in which case you will see one or more `InterpreterNotFound` errors.

Building documentation

`cryptography` documentation is stored in the `docs/` directory. It is written in [reStructured Text](#) and rendered using [Sphinx](#).

Use `tox` to build the documentation. For example:

```
$ tox -e docs  
...  
docs: commands succeeded  
congratulations :)
```

The HTML documentation index can now be found at `docs/_build/html/index.html`.

Submitting patches

- Always make a new branch for your work.
- Patches should be small to facilitate easier review. [Studies have shown](#) that review quality falls off as patch size grows. Sometimes this will result in many small PRs to land a single large feature.
- Larger changes should be discussed on [our mailing list](#) before submission.
- New features and significant bug fixes should be documented in the *Changelog*.
- You must have legal permission to distribute any code you contribute to `cryptography`, and it must be available under both the BSD and Apache Software License Version 2.0 licenses.

If you believe you've identified a security issue in `cryptography`, please follow the directions on the [security page](#).

Code

When in doubt, refer to [PEP 8](#) for Python code. You can check if your code meets our automated requirements by running `flake8` against it. If you've installed the development requirements this will automatically use our configuration. You can also run the `tox` job with `tox -e pep8`.

Write comments as complete sentences.

Class names which contains acronyms or initialisms should always be capitalized. A class should be named `HTTPClient`, not `HttpClient`.

Every code file must start with the boilerplate licensing notice:

```
# This file is dual licensed under the terms of the Apache License, Version
# 2.0, and the BSD License. See the LICENSE file in the root of this repository
# for complete details.
```

Additionally, every Python code file must contain

```
from __future__ import absolute_import, division, print_function
```

API considerations

Most projects' APIs are designed with a philosophy of "make easy things easy, and make hard things possible". One of the perils of writing cryptographic code is that secure code looks just like insecure code, and its results are almost always indistinguishable. As a result, `cryptography` has, as a design philosophy: "make it hard to do insecure things". Here are a few strategies for API design that should be both followed, and should inspire other API choices:

If it is necessary to compare a user provided value with a computed value (for example, verifying a signature), there should be an API provided that performs the verification in a secure way (for example, using a constant time comparison), rather than requiring the user to perform the comparison themselves.

If it is incorrect to ignore the result of a method, it should raise an exception, and not return a boolean `True/False` flag. For example, a method to verify a signature should raise `InvalidSignature`, and not return whether the signature was valid.

```
# This is bad.
def verify(sig):
    # ...
    return is_valid

# Good!
```

```
def verify(sig):
    # ...
    if not is_valid:
        raise InvalidSignature
```

Every recipe should include a version or algorithmic marker of some sort in its output in order to allow transparent upgrading of the algorithms in use, as the algorithms or parameters needed to achieve a given security margin evolve.

APIs at the *Primitives* layer should always take an explicit backend, APIs at the recipes layer should automatically use the `default_backend()`, but optionally allow specifying a different backend.

C bindings

More information on C bindings can be found in *the dedicated section of the documentation*.

Tests

All code changes must be accompanied by unit tests with 100% code coverage (as measured by the combined metrics across our build matrix).

When implementing a new primitive or recipe `cryptography` requires that you provide a set of test vectors. See *Test vectors* for more details.

Documentation

All features should be documented with prose in the `docs` section. To ensure it builds and passes `doc8` style checks you can run `tox -e docs`.

Because of the inherent challenges in implementing correct cryptographic systems, we want to make our documentation point people in the right directions as much as possible. To that end:

- When documenting a generic interface, use a strong algorithm in examples. (e.g. when showing a hashing example, don't use *MD5*)
- When giving prescriptive advice, always provide references and supporting material.
- When there is real disagreement between cryptographic experts, represent both sides of the argument and describe the trade-offs clearly.

When documenting a new module in the `hazmat` package, its documentation should begin with the “Hazardous Materials” warning:

```
.. hazmat::
```

Always prefer terminology that is most broadly accepted. For example:

- When referring to class instances use “an instance of `FOO`” instead of “a `FOO` provider”.

When referring to a hypothetical individual (such as “a person receiving an encrypted message”) use gender neutral pronouns (they/them/their).

Docstrings are typically only used when writing abstract classes, but should be written like this if required:

```
def some_function(some_arg):
    """
    Does some things.
```

```
:param some_arg: Some argument.  
"""
```

So, specifically:

- Always use three double quotes.
- Put the three double quotes on their own line.
- No blank line at the end.
- Use Sphinx parameter/attribute documentation [syntax](#).

Reviewing and merging patches

Everyone is encouraged to review open pull requests. We only ask that you try and think carefully, ask questions and are [excellent to one another](#). Code review is our opportunity to share knowledge, design ideas and make friends.

When reviewing a patch try to keep each of these concepts in mind:

Architecture

- Is the proposed change being made in the correct place? Is it a fix in a backend when it should be in the primitives?

Intent

- What is the change being proposed?
- Do we want this feature or is the bug they're fixing really a bug?

Implementation

- Does the change do what the author claims?
- Are there sufficient tests?
- Has it been documented?
- Will this change introduce new bugs?

Grammar and style

These are small things that are not caught by the automated style checkers.

- Does a variable need a better name?
- Should this be a keyword argument?

Merge requirements

Because cryptography is so complex, and the implications of getting it wrong so devastating, `cryptography` has a strict merge policy for committers:

- Patches must *never* be pushed directly to `master`, all changes (even the most trivial typo fixes!) must be submitted as a pull request.
- A committer may *never* merge their own pull request, a second party must merge their changes. If multiple people work on a pull request, it must be merged by someone who did not work on it.
- A patch that breaks tests, or introduces regressions by changing or removing existing tests should not be merged. Tests must always be passing on `master`.
- If somehow the tests get into a failing state on `master` (such as by a backwards incompatible release of a dependency) no pull requests may be merged until this is rectified.
- All merged patches must have 100% test coverage.

The purpose of these policies is to minimize the chances we merge a change that jeopardizes our users' security.

Test vectors

Testing the correctness of the primitives implemented in each `cryptography` backend requires trusted test vectors. Where possible these vectors are obtained from official sources such as [NIST](#) or [IETF RFCs](#). When this is not possible `cryptography` has chosen to create a set of custom vectors using an official vector file as input to verify consistency between implemented backends.

Vectors are kept in the `cryptography_vectors` package rather than within our main test suite.

Sources

Asymmetric ciphers

- RSA PKCS #1 from the RSA FTP site (<ftp://ftp.rsasecurity.com/pub/pkcs/pkcs-1/> and <ftp://ftp.rsa.com/pub/rsalabs/tmp/>).
- RSA FIPS 186-2 and PKCS1 v1.5 vulnerability test vectors from [NIST CAVP](#).
- FIPS 186-2 and FIPS 186-3 DSA test vectors from [NIST CAVP](#).
- FIPS 186-2 and FIPS 186-3 ECDSA test vectors from [NIST CAVP](#).
- DH and ECDH and ECDH+KDF(17.4) test vectors from [NIST CAVP](#).
- Ed25519 test vectors from the [Ed25519 website](#).
- OpenSSL PEM RSA serialization vectors from the [OpenSSL example key](#) and [GnuTLS key parsing tests](#).
- OpenSSL PEM DSA serialization vectors from the [GnuTLS example keys](#).
- PKCS #8 PEM serialization vectors from
 - GnuTLS: `enc-rsa-pkcs8.pem`, `enc2-rsa-pkcs8.pem`, `unenc-rsa-pkcs8.pem`, `pkcs12_s2k_pem.c`. The contents of `enc2-rsa-pkcs8.pem` was re-encrypted using a stronger PKCS#8 cipher.
 - Botan's ECC private keys.
- `asymmetric/public/PKCS1/dsa.pub.pem` is a PKCS1 DSA public key from the Ruby test suite.
- X25519 test vectors from [RFC 7748](#).

Custom asymmetric vectors

SECP256K1 vector creation

This page documents the code that was used to generate the SECP256K1 elliptic curve test vectors as well as code used to verify them against another implementation.

Creation

The vectors are generated using a [pure Python ecdsa](#) implementation. The test messages and combinations of algorithms are derived from the NIST vector data.

```
from __future__ import absolute_import, print_function

import hashlib
import os
from binascii import hexlify
from collections import defaultdict

from ecdsa import SECP256k1, SigningKey
from ecdsa.util import sigdecode_der, sigencode_der

from cryptography_vectors import open_vector_file

from tests.utils import (
    load_fips_ecdsa_signing_vectors, load_vectors_from_file
)

HASHLIB_HASH_TYPES = {
    "SHA-1": hashlib.sha1,
    "SHA-224": hashlib.sha224,
    "SHA-256": hashlib.sha256,
    "SHA-384": hashlib.sha384,
    "SHA-512": hashlib.sha512,
}

class TruncatedHash(object):
    def __init__(self, hasher):
        self.hasher = hasher

    def __call__(self, data):
        self.hasher.update(data)
        return self

    def digest(self):
        return self.hasher.digest()[:256 // 8]

def build_vectors(fips_vectors):
    vectors = defaultdict(list)
    for vector in fips_vectors:
        vectors[vector['digest_algorithm']].append(vector['message'])

    for digest_algorithm, messages in vectors.items():
        if digest_algorithm not in HASHLIB_HASH_TYPES:
```

```

        continue

    yield ""
    yield "[K-256, {0}].format(digest_algorithm)
    yield ""

    for message in messages:
        # Make a hash context
        hash_func = TruncatedHash(HASHLIB_HASH_TYPES[digest_algorithm]())

        # Sign the message using warner/ecdsa
        secret_key = SigningKey.generate(curve=SECP256k1)
        public_key = secret_key.get_verifying_key()
        signature = secret_key.sign(message, hashfunc=hash_func,
                                    sigencode=sigencode_der)

        r, s = sigdecode_der(signature, None)

        yield "Msg = {0}].format(hexlify(message))

RSA OAEP SHA2 vector creation

This page documents the code that was used to generate the RSA OAEP SHA2 test vectors as well as code used to verify them against another implementation.

Creation

`cryptography` was modified to allow the use of SHA2 in OAEP encryption. Then the following python script was run to generate the vector files.

```
# This file is dual licensed under the terms of the Apache License, Version
# 2.0, and the BSD License. See the LICENSE file in the root of this repository

    }
}

```

```
    } catch (Exception e) {
        // if any exception is thrown the verification has failed
        e.printStackTrace();
        System.out.println("Verification Failed!");
    }
}
}
```

Download link: `VerifyRSOAEP_SHA2.java`

Using the Verifier

Download and install the [Java 8 SDK](#). Initial verification was performed using `jdk-8u77-macosx-x64.dmg`.

Download the latest [Bouncy Castle JAR](#). Initial verification was performed using `bcprov-jdk15on-154.jar`.

Set the `-classpath` to include the Bouncy Castle jar and the path to `VerifyRSOAEP_SHA2.java` and compile the program.

```
$ javac -classpath ~/Downloads/bcprov-jdk15on-154.jar:./ VerifyRSOAEP_SHA2.java
```

Finally, run the program with the path to the SHA-2 vectors:

```
$ java -classpath ~/Downloads/bcprov-jdk15on-154.jar:./ VerifyRSOAEP_SHA2
```

- `asymmetric/PEM_Serialization/ec_private_key.pem` and `asymmetric/DER_Serialization/ec_private_key.der` - Contains an Elliptic Curve key generated by OpenSSL from the curve `secp256r1`.
- `asymmetric/PEM_Serialization/ec_private_key_encrypted.pem` and `asymmetric/DER_Serialization/ec_private_key_encrypted.der` - Contains the same Elliptic Curve key as `ec_private_key.pem`, except that it is encrypted with AES-128 with the password “123456”.
- `asymmetric/PEM_Serialization/ec_public_key.pem` and `asymmetric/DER_Serialization/ec_public_key.der` - Contains the public key corresponding to `ec_private_key.pem`, generated using OpenSSL.
- `asymmetric/PEM_Serialization/rsa_private_key.pem` - Contains an RSA 2048 bit key generated using OpenSSL, protected by the secret “123456” with DES3 encryption.
- `asymmetric/PEM_Serialization/rsa_public_key.pem` and `asymmetric/DER_Serialization/rsa_public_key.der` - Contains an RSA 2048 bit public generated using OpenSSL from `rsa_private_key.pem`.
- `asymmetric/PEM_Serialization/dsaparam.pem` - Contains 2048-bit DSA parameters generated using OpenSSL; contains no keys.
- `asymmetric/PEM_Serialization/dsa_private_key.pem` - Contains a DSA 2048 bit key generated using OpenSSL from the parameters in `dsaparam.pem`, protected by the secret “123456” with DES3 encryption.
- `asymmetric/PEM_Serialization/dsa_public_key.pem` and `asymmetric/DER_Serialization/dsa_public_key.der` - Contains a DSA 2048 bit key generated using OpenSSL from `dsa_private_key.pem`.
- `asymmetric/PKCS8/unenc-dsa-pkcs8.pem` and `asymmetric/DER_Serialization/unenc-dsa-pkcs8.der` - Contains a DSA 1024 bit key generated using OpenSSL.

- `asymmetric/PKCS8/unenc-dsa-pkcs8.pub.pem` and `asymmetric/DER_Serialization/unenc-dsa-pkcs8.pub.der` - Contains a DSA 2048 bit public key generated using OpenSSL from `unenc-dsa-pkcs8.pem`.
- DER conversions of the [GnuTLS example keys](#) for DSA as well as the [OpenSSL example key](#) for RSA.
- DER conversions of `enc-rsa-pkcs8.pem`, `enc2-rsa-pkcs8.pem`, and `unenc-rsa-pkcs8.pem`.
- `asymmetric/public/PKCS1/rsa.pub.pem` and `asymmetric/public/PKCS1/rsa.pub.der` are PKCS1 conversions of the public key from `asymmetric/PKCS8/unenc-rsa-pkcs8.pem` using PEM and DER encoding.

Key exchange

- `vectors/cryptography_vectors/asymmetric/DH/RFC5114.txt` contains Diffie-Hellman examples from appendix A.1, A.2 and A.3 of [RFC 5114](#).
- `vectors/cryptography_vectors/asymmetric/DH/vec.txt` contains Diffie-Hellman examples from [botan](#).
- `vectors/cryptography_vectors/asymmetric/DH/bad_exchange.txt` contains Diffie-Hellman vector pairs that were generated using OpenSSL `DH_generate_parameters_ex` and `DH_generate_key`.
- `vectors/cryptography_vectors/asymmetric/DH/dhp.pem`, `vectors/cryptography_vectors/asymmetric/DH/dhkey.pem` and `vectors/cryptography_vectors/asymmetric/DH/dhpub.pem` contains Diffie-Hellman parameters and key respectively. The keys were generated using OpenSSL following [DHKE](#) guide. `vectors/cryptography_vectors/asymmetric/DH/dhkey.txt` contains all parameter in text. `vectors/cryptography_vectors/asymmetric/DH/dhp.der`, `vectors/cryptography_vectors/asymmetric/DH/dhkey.der` and `vectors/cryptography_vectors/asymmetric/DH/dhpub.der` contains are the above parameters and keys in DER format.
- `vectors/cryptography_vectors/asymmetric/DH/dhp_rfc5114_2.pem`, `vectors/cryptography_vectors/asymmetric/DH/dhkey_rfc5114_2.pem` and `vectors/cryptography_vectors/asymmetric/DH/dhpub_rfc5114_2.pem` contains Diffie-Hellman parameters and key respectively. The keys were generated using OpenSSL following [DHKE](#) guide. When creating the parameters we added the `-pkeyopt dh_rfc5114:2` option to use RFC5114 2048 bit DH parameters with 224 bit subgroup. `vectors/cryptography_vectors/asymmetric/DH/dhkey_rfc5114_2.txt` contains all parameter in text. `vectors/cryptography_vectors/asymmetric/DH/dhp_rfc5114_2.der`, `vectors/cryptography_vectors/asymmetric/DH/dhkey_rfc5114_2.der` and `vectors/cryptography_vectors/asymmetric/DH/dhpub_rfc5114_2.der` contains are the above parameters and keys in DER format.

X.509

- PKITS test suite from [NIST PKI Testing](#).
- `v1_cert.pem` from the OpenSSL source tree (`testx509.pem`).
- `ecdsa_root.pem` - [DigiCert Global Root G3](#), a `secp384r1` ECDSA root certificate.
- `verisign-md2-root.pem` - A legacy Verisign public root signed using the MD2 algorithm. This is a PEM conversion of the [root data](#) in the NSS source tree.
- `cryptography.io.pem` - A leaf certificate issued by RapidSSL for the cryptography website.

- `rapidssl_sha256_ca_g3.pem` - The intermediate CA that issued the `cryptography.io.pem` certificate.
- `wildcard_san.pem` - A leaf certificate issued by a public CA for `langui.sh` that contains wildcard entries in the SAN extension.
- `san_edipartyname.der` - A DSA certificate from a [Mozilla bug](#) containing a SAN extension with an `ediPartyName` general name.
- `san_x400address.der` - A DSA certificate from a [Mozilla bug](#) containing a SAN extension with an `x400Address` general name.
- `department-of-state-root.pem` - The intermediary CA for the Department of State, issued by the United States Federal Government's Common Policy CA. Notably has a `critical` policy constraints extensions.
- `e-trust.ru.der` - A certificate from a [Russian CA](#) signed using the GOST cipher and containing numerous unusual encodings such as `NUMERICSTRING` in the subject DN.
- `alternate-rsa-sha1-oid.pem` - A certificate from an [unknown signature OID Mozilla bug](#) that uses an alternate signature OID for RSA with SHA1.
- `badssl-sct.pem` - A certificate with the certificate transparency signed certificate timestamp extension.
- `bigoid.pem` - A certificate with a rather long OID in the Certificate Policies extension. We need to make sure we can parse long OIDs.

Custom X.509 Vectors

- `invalid_version.pem` - Contains an RSA 2048 bit certificate with the X.509 version field set to `0x7`.
- `post2000utctime.pem` - Contains an RSA 2048 bit certificate with the `notBefore` and `notAfter` fields encoded as post-2000 `UTCTime`.
- `dsa_selfsigned_ca.pem` - Contains a DSA self-signed CA certificate generated using OpenSSL.
- `ec_no_named_curve.pem` - Contains an ECDSA certificate that does not have an embedded OID defining the curve.
- `all_supported_names.pem` - An RSA 2048 bit certificate generated using OpenSSL that contains a subject and issuer that have two of each supported attribute type from [RFC 5280](#).
- `unsupported_subject_name.pem` - An RSA 2048 bit self-signed CA certificate generated using OpenSSL that contains the unsupported "initials" name.
- `utf8_common_name.pem` - An RSA 2048 bit self-signed CA certificate generated using OpenSSL that contains a `UTF8String` common name with the value "We heart UTF8!™".
- `two_basic_constraints.pem` - An RSA 2048 bit self-signed certificate containing two basic constraints extensions.
- `basic_constraints_not_critical.pem` - An RSA 2048 bit self-signed certificate containing a basic constraints extension that is not marked as critical.
- `bc_path_length_zero.pem` - An RSA 2048 bit self-signed certificate containing a basic constraints extension with a path length of zero.
- `unsupported_extension.pem` - An RSA 2048 bit self-signed certificate containing an unsupported extension type. The OID was encoded as "1.2.3.4" with an `extnValue` of "value".

- `unsupported_extension_2.pem` - A `secp256r1` certificate containing two unsupported extensions. The OIDs are `1.3.6.1.4.1.41482.2` with an `extnValue` of `1.3.6.1.4.1.41482.1.2` and `1.3.6.1.4.1.45724.2.1.1` with an `extnValue` of `\x03\x02\x040`
- `unsupported_extension_critical.pem` - An RSA 2048 bit self-signed certificate containing an unsupported extension type marked critical. The OID was encoded as “1.2.3.4” with an `extnValue` of “value”.
- `san_email_dns_ip_dirname_uri.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with the following general names: `rfc822Name`, `dNSName`, `iPAddress`, `directoryName`, and `uniformResourceIdentifier`.
- `san_empty_hostname.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative extension with an empty `dNSName` general name.
- `san_other_name.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with the `otherName` general name.
- `san_registered_id.pem` - An RSA 1024 bit certificate containing a subject alternative name extension with the `registeredID` general name.
- `all_key_usages.pem` - An RSA 2048 bit self-signed certificate containing a key usage extension with all nine purposes set to true.
- `extended_key_usage.pem` - An RSA 2048 bit self-signed certificate containing an extended key usage extension with eight usages.
- `san_idna_names.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with `rfc822Name`, `dNSName`, and `uniformResourceIdentifier` general names with IDNA (RFC 5895) encoding.
- `san_wildcard_idna.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with a `dNSName` general name with a wildcard IDNA (RFC 5895) domain.
- `san_idna2003_dnsname.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with an IDNA 2003 (RFC 3490) `dNSName`.
- `san_rfc822_names.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with various `rfc822Name` values.
- `san_rfc822_idna.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with an IDNA `rfc822Name`.
- `san_uri_with_port.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with various `uniformResourceIdentifier` values.
- `san_ipaddr.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with an `iPAddress` value.
- `san_dirname.pem` - An RSA 2048 bit self-signed certificate containing a subject alternative name extension with a `directoryName` value.
- `inhibit_any_policy_5.pem` - An RSA 2048 bit self-signed certificate containing an inhibit any policy extension with the value 5.
- `inhibit_any_policy_negative.pem` - An RSA 2048 bit self-signed certificate containing an inhibit any policy extension with the value -1.
- `authority_key_identifier.pem` - An RSA 2048 bit self-signed certificate containing an authority key identifier extension with key identifier, authority certificate issuer, and authority certificate serial number fields.
- `authority_key_identifier_no_keyid.pem` - An RSA 2048 bit self-signed certificate containing an authority key identifier extension with authority certificate issuer and authority certificate serial number fields.

- `aia_ocsp_ca_issuers.pem` - An RSA 2048 bit self-signed certificate containing an authority information access extension with two OCSP and one CA issuers entry.
- `aia_ocsp.pem` - An RSA 2048 bit self-signed certificate containing an authority information access extension with an OCSP entry.
- `aia_ca_issuers.pem` - An RSA 2048 bit self-signed certificate containing an authority information access extension with a CA issuers entry.
- `cdp_empty_hostname.pem` - An RSA 2048 bit self-signed certificate containing a CRL distribution point extension with `fullName` URI without a hostname.
- `cdp_fullname_reasons_crl_issuer.pem` - An RSA 1024 bit certificate containing a CRL distribution points extension with `fullName`, `cRLIssuer`, and `reasons` data.
- `cdp_crl_issuer.pem` - An RSA 1024 bit certificate containing a CRL distribution points extension with `cRLIssuer` data.
- `cdp_all_reasons.pem` - An RSA 1024 bit certificate containing a CRL distribution points extension with all reasons bits set.
- `cdp_reason_aa_compromise.pem` - An RSA 1024 bit certificate containing a CRL distribution points extension with the `AACompromise` reasons bit set.
- `nc_permitted_excluded.pem` - An RSA 2048 bit self-signed certificate containing a name constraints extension with both permitted and excluded elements. Contains IPv4 and IPv6 addresses with network mask as well as `dnsName` with a leading period.
- `nc_permitted_excluded_2.pem` - An RSA 2048 bit self-signed certificate containing a name constraints extension with both permitted and excluded elements. Unlike `nc_permitted_excluded.pem`, the general names do not contain any name constraints specific values.
- `nc_permitted.pem` - An RSA 2048 bit self-signed certificate containing a name constraints extension with permitted elements.
- `nc_permitted_2.pem` - An RSA 2048 bit self-signed certificate containing a name constraints extension with permitted elements that do not contain any name constraints specific values.
- `nc_excluded.pem` - An RSA 2048 bit self-signed certificate containing a name constraints extension with excluded elements.
- `nc_invalid_ip_netmask.pem` - An RSA 2048 bit self-signed certificate containing a name constraints extension with a permitted element that has an IPv6 IP and an invalid network mask.
- `nc_single_ip_netmask.pem` - An RSA 2048 bit self-signed certificate containing a name constraints extension with a permitted element that has two IPs with /32 and /128 network masks.
- `cp_user_notice_with_notice_reference.pem` - An RSA 2048 bit self-signed certificate containing a certificate policies extension with a notice reference in the user notice.
- `cp_user_notice_with_explicit_text.pem` - An RSA 2048 bit self-signed certificate containing a certificate policies extension with explicit text and no notice reference.
- `cp_cps_uri.pem` - An RSA 2048 bit self-signed certificate containing a certificate policies extension with a CPS URI and no user notice.
- `cp_user_notice_no_explicit_text.pem` - An RSA 2048 bit self-signed certificate containing a certificate policies extension with a user notice with no explicit text.
- `cp_invalid.pem` - An RSA 2048 bit self-signed certificate containing a certificate policies extension with invalid data.
- `ian_uri.pem` - An RSA 2048 bit certificate containing an issuer alternative name extension with a URI general name.

- `ocsp_nocheck.pem` - An RSA 2048 bit self-signed certificate containing an `OCSPNoCheck` extension.
- `pc_inhibit_require.pem` - An RSA 2048 bit self-signed certificate containing a policy constraints extension with both inhibit policy mapping and require explicit policy elements.
- `pc_inhibit.pem` - An RSA 2048 bit self-signed certificate containing a policy constraints extension with an inhibit policy mapping element.
- `pc_require.pem` - An RSA 2048 bit self-signed certificate containing a policy constraints extension with a require explicit policy element.
- `unsupported_subject_public_key_info.pem` - A certificate whose public key is an unknown OID (1.3.6.1.4.1.8432.1.1.2).
- `policy_constraints_explicit.pem` - A self-signed certificate containing a `policyConstraints` extension with a `requireExplicitPolicy` value.

Custom X.509 Request Vectors

- `dsa_sha1.pem` and `dsa_sha1.der` - Contain a certificate request using 1024-bit DSA parameters and SHA1 generated using OpenSSL.
- `rsa_md4.pem` and `rsa_md4.der` - Contain a certificate request using 2048 bit RSA and MD4 generated using OpenSSL.
- `rsa_sha1.pem` and `rsa_sha1.der` - Contain a certificate request using 2048 bit RSA and SHA1 generated using OpenSSL.
- `rsa_sha256.pem` and `rsa_sha256.der` - Contain a certificate request using 2048 bit RSA and SHA256 generated using OpenSSL.
- `ec_sha256.pem` and `ec_sha256.der` - Contain a certificate request using EC (`secp384r1`) and SHA256 generated using OpenSSL.
- `san_rsa_sha1.pem` and `san_rsa_sha1.der` - Contain a certificate request using RSA and SHA1 with a subject alternative name extension generated using OpenSSL.
- `two_basic_constraints.pem` - A certificate signing request for an RSA 2048 bit key containing two basic constraints extensions.
- `unsupported_extension.pem` - A certificate signing request for an RSA 2048 bit key containing containing an unsupported extension type. The OID was encoded as “1.2.3.4” with an `extnValue` of “value”.
- `unsupported_extension_critical.pem` - A certificate signing request for an RSA 2048 bit key containing containing an unsupported extension type marked critical. The OID was encoded as “1.2.3.4” with an `extnValue` of “value”.
- `basic_constraints.pem` - A certificate signing request for an RSA 2048 bit key containing a basic constraints extension marked as critical.
- `invalid_signature.pem` - A certificate signing request for an RSA 1024 bit key containing an invalid signature with correct padding.

Custom X.509 Certificate Revocation List Vectors

- `crl_all_reasons.pem` - Contains a CRL with 12 revoked certificates, whose serials match their list position. It includes one revocation without any entry extensions, 10 revocations with every supported reason code and one revocation with an unsupported, non-critical entry extension with the OID value set to “1.2.3.4”.
- `crl_dup_entry_ext.pem` - Contains a CRL with one revocation which has a duplicate entry extension.

- `crl_md2_unknown_crit_entry_ext.pem` - Contains a CRL with one revocation which contains an unsupported critical entry extension with the OID value set to “1.2.3.4”. The CRL uses an unsupported MD2 signature algorithm.
- `crl_unsupported_reason.pem` - Contains a CRL with one revocation which has an unsupported reason code.
- `crl_inval_cert_issuer_entry_ext.pem` - Contains a CRL with one revocation which has one entry extension for certificate issuer with an empty value.
- `crl_empty.pem` - Contains a CRL with no revoked certificates.
- `crl_ian_aia_aki.pem` - Contains a CRL with `IssuerAlternativeName`, `AuthorityInformationAccess`, `AuthorityKeyIdentifier` and `CRLNumber` extensions.

Hashes

- MD5 from [RFC 1321](#).
- RIPEMD160 from the [RIPEMD website](#).
- SHA1 from [NIST CAVP](#).
- SHA2 (224, 256, 384, 512) from [NIST CAVP](#).
- Whirlpool from the [Whirlpool website](#).
- Blake2s and Blake2b from OpenSSL [test/evptests.txt](#).

HMAC

- HMAC-MD5 from [RFC 2202](#).
- HMAC-SHA1 from [RFC 2202](#).
- HMAC-RIPEMD160 from [RFC 2286](#).
- HMAC-SHA2 (224, 256, 384, 512) from [RFC 4231](#).

Key derivation functions

- HKDF (SHA1, SHA256) from [RFC 5869](#).
- PBKDF2 (HMAC-SHA1) from [RFC 6070](#).
- `scrypt` from the [draft RFC](#).
- X9.63 KDF from [NIST CAVP](#).
- SP 800-108 Counter Mode KDF (HMAC-SHA1, HMAC-SHA224, HMAC-SHA256, HMAC-SHA384, HMAC-SHA512) from [NIST CAVP](#).

Key wrapping

- AES key wrap (AESKW) and 3DES key wrap test vectors from [NIST CAVP](#).

Recipes

- Fernet from its [specification repository](#).

Symmetric ciphers

- AES (CBC, CFB, ECB, GCM, OFB, CCM) from [NIST CAVP](#).
- AES CTR from [RFC 3686](#).
- 3DES (CBC, CFB, ECB, OFB) from [NIST CAVP](#).
- ARC4 (KEY-LENGTH: 40, 56, 64, 80, 128, 192, 256) from [RFC 6229](#).
- ARC4 (KEY-LENGTH: 160) generated by this project. See: [ARC4 vector creation](#)
- Blowfish (CBC, CFB, ECB, OFB) from [Bruce Schneier's vectors](#).
- Camellia (ECB) from [NTT's Camellia page](#) as linked by [CRYPTREC](#).
- Camellia (CBC, CFB, OFB) from [OpenSSL's test vectors](#).
- CAST5 (ECB) from [RFC 2144](#).
- CAST5 (CBC, CFB, OFB) generated by this project. See: [CAST5 vector creation](#)
- ChaCha20Poly1305 from [RFC 7539](#), [OpenSSL's evpciph.txt](#), and the [BoringSSL ChaCha20Poly1305 tests](#).
- IDEA (ECB) from the [NESSIE IDEA vectors](#) created by [NESSIE](#).
- IDEA (CBC, CFB, OFB) generated by this project. See: [IDEA vector creation](#)
- SEED (ECB) from [RFC 4269](#).
- SEED (CBC) from [RFC 4196](#).
- SEED (CFB, OFB) generated by this project. See: [SEED vector creation](#)

Two factor authentication

- HOTP from [RFC 4226](#)
- TOTP from [RFC 6238](#) (Note that an [errata](#) for the test vectors in RFC 6238 exists)

CMAC

- AES-128, AES-192, AES-256, 3DES from [NIST SP-800-38B](#)

Creating test vectors

When official vectors are unavailable cryptography may choose to build its own using existing vectors as source material.

Custom Symmetric Vectors

ARC4 vector creation

This page documents the code that was used to generate the ARC4 test vectors for key lengths not available in RFC 6229. All the vectors were generated using OpenSSL and verified with Go.

Creation

cryptography was modified to support ARC4 key lengths not listed in RFC 6229. Then the following Python script was run to generate the vector files.

```

CAST5 vector creation

This page documents the code that was used to generate the CAST5 CBC, CFB, OFB, and CTR test vectors as well as the code used to verify them against another implementation. The CBC, CFB, and OFB vectors were generated using OpenSSL and the CTR vectors were generated using Apple's CommonCrypto. All the generated vectors were verified with Go.

Creation

cryptography was modified to support CAST5 in CBC, CFB, and OFB modes. Then the following Python script was run to generate the vector files.

```

Verification

The following Python code was used to verify the vectors using the [Botan](#) project's Python bindings.

```
import binascii

import botan

from tests.utils import load_nist_vectors

def encrypt(mode, key, iv, plaintext):
    encryptor = botan.Cipher("SEED/{0}/NoPadding".format(mode), "encrypt",
                             binascii.unhexlify(key))

    cipher_text = encryptor.cipher(binascii.unhexlify(plaintext),
                                   binascii.unhexlify(iv))
    return binascii.hexlify(cipher_text)

def verify_vectors(mode, filename):
    with open(filename, "r") as f:
        vector_file = f.read().splitlines()

    vectors = load_nist_vectors(vector_file)
    for vector in vectors:
        ct = encrypt(
            mode,
            vector["key"],
            vector["iv"],
            vector["plaintext"]
        )
        assert ct == vector["ciphertext"]

ofb_path = "vectors/cryptography_vectors/ciphers/SEED/seed-ofb.txt"
verify_vectors("OFB", ofb_path)
cfb_path = "vectors/cryptography_vectors/ciphers/SEED/seed-cfb.txt"
verify_vectors("CFB", cfb_path)
```

Download link: [verify_seed.py](#)

If official test vectors appear in the future the custom generated vectors should be discarded.

Any vectors generated by this method must also be prefixed with the following header format (substituting the correct information):

```
# CAST5 CBC vectors built for https://github.com/pyca/cryptography
# Derived from the AESVS MMT test data for CBC
# Verified against the CommonCrypto and Go crypto packages
# Key Length : 128
```

C bindings

C bindings are bindings to C libraries, using `ctypes` whenever possible.

Bindings live in `cryptography.hazmat.bindings`.

When modifying the bindings you will need to recompile the C extensions to test the changes. This can be accomplished with `pip install -e .` in the project root. If you do not do this a `RuntimeError` will be raised.

Style guide

Don't name parameters:

```
/* Good */
long f(long);
/* Bad */
long f(long x);
```

...unless they're inside a struct:

```
struct my_struct {
    char *name;
    int number;
    ...;
};
```

Include `void` if the function takes no arguments:

```
/* Good */
long f(void);
/* Bad */
long f();
```

Wrap lines at 80 characters like so:

```
/* Pretend this went to 80 characters */
long f(long, long,
       int *)
```

Include a space after commas between parameters:

```
/* Good */
long f(int, char *)
/* Bad */
long f(int, char *)
```

Use C-style `/* */` comments instead of C++-style `//`:

```
// Bad
/* Good */
```

Values set by `#define` should be assigned the appropriate type. If you see this:

```
#define SOME_INTEGER_LITERAL 0x0;
#define SOME_UNSIGNED_INTEGER_LITERAL 0x0001U;
#define SOME_STRING_LITERAL "hello";
```

...it should be added to the bindings like so:

```
static const int SOME_INTEGER_LITERAL;
static const unsigned int SOME_UNSIGNED_INTEGER_LITERAL;
static const char *const SOME_STRING_LITERAL;
```

Adding constant, types, functions...

You can create bindings for any name that exists in some version of the library you're binding against. However, the project also has to keep supporting older versions of the library. In order to achieve this, binding modules have a `CUSTOMIZATIONS` constant, and there is a `CONDITIONAL_NAMES` constants in `src/cryptography/hazmat/bindings/openssl/_conditional.py`.

Let's say you want to enable quantum transmogrification. The upstream library implements this as the following API:

```
static const int QM_TRANSMOGRIFICATION_ALIGNMENT_LEFT;
static const int QM_TRANSMOGRIFICATION_ALIGNMENT_RIGHT;
typedef ... QM_TRANSMOGRIFICATION_CTX;
int QM_transmogrify(QM_TRANSMOGRIFICATION_CTX *, int);
```

To start, create a new constant that defines if the *actual* library has the feature you want, and add it to `TYPES`:

```
static const long Cryptography_HAS_QUANTUM_TRANSMOGRIFICATION;
```

This should start with `Cryptography_`, since we're adding it in this library. This prevents namespace collisions.

Then, define the actual features (constants, types, functions...) you want to expose. If it's a constant, just add it to `TYPES`:

```
static const int QM_TRANSMOGRIFICATION_ALIGNMENT_LEFT;
static const int QM_TRANSMOGRIFICATION_ALIGNMENT_RIGHT;
```

If it's a struct, add it to `TYPES` as well. The following is an opaque struct:

```
typedef ... QM_TRANSMOGRIFICATION_CTX;
```

... but you can also make some or all items in the struct accessible:

```
typedef struct {
    /* Fundamental constant k for your particular universe */
    BIGNUM *k;
    ...;
} QM_TRANSMOGRIFICATION_CTX;
```

Confusingly, functions that aren't always available on all supported versions of the library, should be defined in `MACROS` and *not* in `FUNCTIONS`. Fortunately, you just have to copy the signature:

```
int QM_transmogrify(QM_TRANSMOGRIFICATION_CTX *, int);
```

Then, we define the `CUSTOMIZATIONS` entry. To do that, we have to come up with a C preprocessor expression that decides whether or not a feature exists in the library. For example:

```
#ifdef QM_transmogrify
```

Then, we set the flag that signifies the feature exists:

```
static const long Cryptography_HAS_QUANTUM_TRANSMOGRIFICATION = 1;
```

Otherwise, we set that flag to 0:

```
#else
static const long Cryptography_HAS_QUANTUM_TRANSMOGRIFICATION = 0;
```

Then, in that `#else` block, we define the names that aren't available as dummy values. For an integer constant, use 0:

```
static const int QM_TRANSMOGRIFICATION_ALIGNMENT_LEFT = 0;
static const int QM_TRANSMOGRIFICATION_ALIGNMENT_RIGHT = 0;
```

For a function, it's a bit trickier. You have to define a function pointer of the appropriate type to be NULL:

```
int (*QM_transmoglify)(QM_TRANSMOGRIFICATION_CTX *, int) = NULL;
```

(To do that, copy the signature, put a `*` in front of the function name and wrap it in parentheses, and then put `= NULL` at the end).

Note how types don't need to be conditionally defined, as long as all the necessarily type definitions are in place.

Finally, add an entry to `CONDITIONAL_NAMES` with all of the things you want to conditionally export:

```
CONDITIONAL_NAMES = {
    ...
    "Cryptography_HAS_QUANTUM_TRANSMOGRIFICATION": [
        "QM_TRANSMOGRIFICATION_ALIGNMENT_LEFT",
        "QM_TRANSMOGRIFICATION_ALIGNMENT_RIGHT",
        "QM_transmoglify"
    ]
}
```

Caveats

Sometimes, a set of loosely related features are added in the same version, and it's impractical to create `#ifdef` statements for each one. In that case, it may make sense to either check for a particular version. For example, to check for OpenSSL 1.1.0 or newer:

```
#if OPENSSL_VERSION_NUMBER >= 0x10100000L
```

Sometimes, the version of a library on a particular platform will have features that you thought it wouldn't, based on its version. Occasionally, packagers appear to ship arbitrary VCS checkouts. As a result, sometimes you may have to add separate `#ifdef` statements for particular features. This kind of issue is typically only caught by running the tests on a wide variety of systems, which is the job of our continuous integration infrastructure.

Security

We take the security of `cryptography` seriously. The following are a set of policies we have adopted to ensure that security issues are addressed in a timely fashion.

What is a security issue?

Anytime it's possible to write code using `cryptography`'s public API which does not provide the guarantees that a reasonable developer would expect it to based on our documentation.

That's a bit academic, but basically it means the scope of what we consider a vulnerability is broad, and we do not require a proof of concept or even a specific exploit, merely a reasonable threat model under which `cryptography` could be attacked.

To give a few examples of things we would consider security issues:

- If a recipe, such as Fernet, made it easy for a user to bypass confidentiality or integrity with the public API (e.g. if the API let a user reuse nonces).

- If, under any circumstances, we used a CSPRNG which wasn't fork-safe.
- If `cryptography` used an API in an underlying C library and failed to handle error conditions safely.

Examples of things we wouldn't consider security issues:

- Offering ECB mode for symmetric encryption in the *Hazmat* layer. Though ECB is critically weak, it is documented as being weak in our documentation.
- Using a variable time comparison somewhere, if it's not possible to articulate any particular program in which this would result in problematic information disclosure.

In general, if you're unsure, we request that you default to treating things as security issues and handling them sensitively, the worst thing that can happen is that we'll ask you to file a public issue.

Reporting a security issue

We ask that you do not report security issues to our normal GitHub issue tracker.

If you believe you've identified a security issue with `cryptography`, please report it to `alex.gaynor@gmail.com`. Messages may be optionally encrypted with PGP using key fingerprint `F7FC 698F AAE2 D2EF BECD E98E D1B3 ADC0 E023 8CA6` (this public key is available from most commonly-used key servers).

Once you've submitted an issue via email, you should receive an acknowledgment within 48 hours, and depending on the action to be taken, you may receive further follow-up emails.

Supported Versions

At any given time, we will provide security support for the `master` branch as well as the most recent release.

New releases for OpenSSL updates

As of version 0.5, `cryptography` statically links OpenSSL on Windows, and as of version 1.0.1 on macOS, to ease installation. Due to this, `cryptography` will release a new version whenever OpenSSL has a security or bug fix release to avoid shipping insecure software.

Like all our other releases, this will be announced on the mailing list and we strongly recommend that you upgrade as soon as possible.

Disclosure Process

Our process for taking a security issue from private discussion to public disclosure involves multiple steps.

Approximately one week before full public disclosure, we will send advance notification of the issue to a list of people and organizations, primarily composed of operating-system vendors and other distributors of `cryptography`. This notification will consist of an email message containing:

- A full description of the issue and the affected versions of `cryptography`.
- The steps we will be taking to remedy the issue.
- The patches, if any, that will be applied to `cryptography`.
- The date on which the `cryptography` team will apply these patches, issue new releases, and publicly disclose the issue.

Simultaneously, the reporter of the issue will receive notification of the date on which we plan to take the issue public.

On the day of disclosure, we will take the following steps:

- Apply the relevant patches to the `cryptography` repository. The commit messages for these patches will indicate that they are for security issues, but will not describe the issue in any detail; instead, they will warn of upcoming disclosure.
- Issue the relevant releases.
- Post a notice to the `cryptography` mailing list that describes the issue in detail, point to the new release and crediting the reporter of the issue.

If a reported issue is believed to be particularly time-sensitive – due to a known exploit in the wild, for example – the time between advance notification and public disclosure may be shortened considerably.

The list of people and organizations who receives advanced notification of security issues is not and will not be made public. This list generally consists of high-profile downstream distributors and is entirely at the discretion of the `cryptography` team.

Known security limitations

Lack of secure memory wiping

`Memory wiping` is used to protect secret data or key material from attackers with access to uninitialized memory. This can be either because the attacker has some kind of local user access or because of how other software uses uninitialized memory.

Python exposes no API for us to implement this reliably and as such almost all software in Python is potentially vulnerable to this attack. The [CERT secure coding guidelines](#) assesses this issue as “Severity: medium, Likelihood: unlikely, Remediation Cost: expensive to repair” and we do not consider this a high risk for most users.

API stability

From its first release, `cryptography` will have a strong API stability policy.

What does this policy cover?

This policy includes any API or behavior that is documented in this documentation.

What does “stable” mean?

- Public APIs will not be removed or renamed without providing a compatibility alias.
- The behavior of existing APIs will not change.

What doesn’t this policy cover?

- We may add new features, things like the result of `dir(obj)` or the contents of `obj.__dict__` may change.

- Objects are not guaranteed to be pickleable, and pickled objects from one version of `cryptography` may not be loadable in future versions.
- Development versions of `cryptography`. Before a feature is in a release, it is not covered by this policy and may change.

Security

One exception to our API stability policy is for security. We will violate this policy as necessary in order to resolve a security issue or harden `cryptography` against a possible attack.

Deprecation

From time to time we will want to change the behavior of an API or remove it entirely. In that case, here's how the process will work:

- In `cryptography X.Y` the feature exists.
- In `cryptography X.Y+1` using that feature will emit a `PendingDeprecationWarning`.
- In `cryptography X.Y+2` using that feature will emit a `DeprecationWarning`.
- In `cryptography X.Y+3` the feature will be removed or changed.

In short, code that runs without warnings will always continue to work for a period of two releases.

From time to time, we may decide to deprecate an API that is particularly widely used. In these cases, we may decide to provide an extended deprecation period, at our discretion.

Doing a release

Doing a release of `cryptography` requires a few steps.

Verifying and upgrading OpenSSL version

The release process uses a static build for Windows and macOS wheels. Check that the Windows and macOS Jenkins builders have the latest version of OpenSSL installed before performing the release. If they do not:

Upgrading Windows

Run the `openssl-release-1.1` Jenkins job, then copy the resulting artifacts to the Windows builders and unzip them in the root of the file system.

Upgrading macOS

Run the `update-brew-openssl` Jenkins job.

Bumping the version number

The next step in doing a release is bumping the version number in the software.

- Update the version number in `src/cryptography/___about__.py`.
- Update the version number in `vectors/cryptography_vectors/___about__.py`.
- Set the release date in the *Changelog*.
- Do a commit indicating this.
- Send a pull request with this.
- Wait for it to be merged.

Performing the release

The commit that merged the version number bump is now the official release commit for this release. You will need to have `gpg` installed and a `gpg` key in order to do a release. Once this has happened:

- Run `python release.py {version}`.

The release should now be available on PyPI and a tag should be available in the repository.

Verifying the release

You should verify that `pip install cryptography` works correctly:

```
>>> import cryptography
>>> cryptography.__version__
'...'
>>> import cryptography_vectors
>>> cryptography_vectors.__version__
'...'
```

Verify that this is the version you just released.

For the Windows wheels check the builds for the `cryptography-wheel-builder` job and verify that the final output for each build shows it loaded and linked the expected OpenSSL version.

Post-release tasks

- Update the version number to the next major (e.g. `0.5.dev1`) in `cryptography/___about__.py` and `vectors/cryptography_vectors/___about__.py`.
- Close the [milestone](#) for the previous release on GitHub.
- Add new *Changelog* entry with next version and note that it is under active development
- Send a pull request with these items
- Check for any outstanding code undergoing a deprecation cycle by looking in `cryptography.utils` for `DeprecatedIn**` definitions. If any exist open a ticket to increment them for the next release.
- Send an email to the [mailing list](#) and [python-announce](#) announcing the release.

Community

You can find cryptography all over the web:

- [Mailing list](#)
- [Source code](#)
- [Issue tracker](#)
- [Documentation](#)
- IRC: `#cryptography-dev` on `irc.freenode.net`

Wherever we interact, we adhere to the [Python Community Code of Conduct](#).

Glossary

authentication The process of verifying that a message was created by a specific individual (or program). Like encryption, authentication can be either symmetric or asymmetric. Authentication is necessary for effective encryption.

ciphertext The encoded data, it's not user readable. Potential attackers are able to see this.

ciphertext indistinguishability This is a property of encryption systems whereby two encrypted messages aren't distinguishable without knowing the encryption key. This is considered a basic, necessary property for a working encryption system.

decryption The process of converting ciphertext to plaintext.

encryption The process of converting plaintext to ciphertext.

key Secret data is encoded with a function using this key. Sometimes multiple keys are used. These **must** be kept secret, if a key is exposed to an attacker, any data encrypted with it will be exposed.

nonce A nonce is a **number** used **once**. Nonces are used in many cryptographic protocols. Generally, a nonce does not have to be secret or unpredictable, but it must be unique. A nonce is often a random or pseudo-random number (see *Random number generation*). Since a nonce does not have to be unpredictable, it can also take a form of a counter.

plaintext User-readable data you care about.

private key This is one of two keys involved in *public-key cryptography*. It can be used to decrypt messages which were encrypted with the corresponding *public key*, as well as to create signatures, which can be verified with the corresponding *public key*. These **must** be kept secret, if they are exposed, all encrypted messages are compromised, and an attacker will be able to forge signatures.

public key This is one of two keys involved in *public-key cryptography*. It can be used to encrypt messages for someone possessing the corresponding *private key* and to verify signatures created with the corresponding *private key*. This can be distributed publicly, hence the name.

public-key cryptography

asymmetric cryptography Cryptographic operations where encryption and decryption use different keys. There are separate encryption and decryption keys. Typically encryption is performed using a *public key*, and it can then be decrypted using a *private key*. Asymmetric cryptography can also be used to create signatures, which can be generated with a *private key* and verified with a *public key*.

symmetric cryptography Cryptographic operations where encryption and decryption use the same key.

text This type corresponds to `unicode` on Python 2 and `str` on Python 3. This is equivalent to `six.text_type`.

Note: cryptography has not been subjected to an external audit of its code or documentation. If you're interested in discussing an audit please *get in touch*.
