InfluxDB is an open-source distributed time series database, find more about InfluxDB at https://docs.influxdata.com/influxdb/latest

InfluxDB pre v1.1.0 users

This module is tested with InfluxDB v1.2.4, our recommended version. Though there have been v1.3 (initial TSI branch) and v1.4 releases these are not yet supported.

Those users still on InfluxDB v0.8.x users may still use the legacy client by importing from influxdb.

    influxdb08 import InfluxDBClient.

Installation

Install, upgrade and uninstall influxdb-python with these commands:

    $ pip install influxdb
    $ pip install --upgrade influxdb
    $ pip uninstall influxdb

On Debian/Ubuntu, you can install it with this command:
$ sudo apt-get install python-influxdb

**Dependencies**

The influxdb-python distribution is supported and tested on Python 2.7, 3.3, 3.4, 3.5, 3.6, PyPy and PyPy3.

**Note:** Python 3.2 is currently untested. See `.travis.yml`.

Main dependency is:

- Requests: HTTP library for human beings (http://docs.python-requests.org/)

Additional dependencies are:

- pandas: for writing from and reading to DataFrames (http://pandas.pydata.org/)
- Sphinx: Tool to create and manage the documentation (http://sphinx-doc.org/)
- Nose: to auto-discover tests (http://nose.readthedocs.org/en/latest/)
- Mock: to mock tests (https://pypip.python.org/pypip/mock)

**Documentation**

Documentation is available at https://influxdb-python.readthedocs.io/en/latest/.

You will need Sphinx installed to generate the documentation.

The documentation can be generated by running:

```
$ tox -e docs
```

Generated documentation can be found in the *docs/build/html/* directory.

**Examples**

Here’s a basic example (for more see the examples directory):

```
$ python
>>> from influxdb import InfluxDBClient

>>> json_body = [
    {
        "measurement": "cpu_load_short",
        "tags": {
            "host": "server01",
            "region": "us-west"
        },
        "time": "2009-11-10T23:00:00Z",
        "fields": {
            "value": 0.64
        }
    }
]

>>> client = InfluxDBClient('localhost', 8086, 'root', 'root', 'example')
```
InfluxDB Documentation, Release 4.1.1

```python
>>> client.create_database('example')
>>> client.write_points(json_body)
>>> result = client.query('select value from cpu_load_short;')
>>> print("Result: {0}".format(result))
```

Testing

Make sure you have tox by running the following:

```
$ pip install tox
```

To test influxdb-python with multiple version of Python, you can use `Tox`:

```
$ tox
```

Support

For issues with, questions about, or feedback for InfluxDB, please look into our community page: http://influxdb.com/community/.

We are also lurking on the following:

- #influxdb on irc.freenode.net
- #influxdb on gophers.slack.com

Development

All development is done on Github. Use Issues to report problems or submit contributions.

Please note that we WILL get to your questions/issues/concerns as quickly as possible. We maintain many software repositories and sometimes things may get pushed to the backburner. Please don’t take offense, we will do our best to reply as soon as possible!

The source code is currently available on Github: https://github.com/influxdata/influxdb-python

TODO

The TODO/Roadmap can be found in Github bug tracker: https://github.com/influxdata/influxdb-python/issues

API Documentation

To connect to a InfluxDB, you must create a `InfluxDBClient` object. The default configuration connects to InfluxDB on `localhost` with the default ports. The below instantiation statements are all equivalent:
```python
from influxdb import InfluxDBClient

# using Http
client = InfluxDBClient(database='dbname')
client = InfluxDBClient(host='127.0.0.1', port=8086, database='dbname')
client = InfluxDBClient(host='127.0.0.1', port=8086, username='root', password='root',
                        database='dbname')

# using UDP
client = InfluxDBClient(host='127.0.0.1', database='dbname', use_udp=True, udp_port=4444)
```

To write pandas DataFrames or to read data into a pandas DataFrame, use a \texttt{DataFrameClient} object. These clients are initiated in the same way as the \texttt{InfluxDBClient}:

```python
from influxdb import DataFrameClient
client = DataFrameClient(host='127.0.0.1', port=8086, username='root', password='root',
                         database='dbname')
```

**Note:** Only when using UDP (use\_udp=True) the connections is established.

### InfluxDBClient

class \texttt{influxdb.InfluxDBClient} (host=u'localhost', port=8086, username=u'root', password=u'root',
database=None, ssl=False, verify\_ssl=False, timeout=None, retries=3, use\_udp=False, udp\_port=4444, proxies=None)

InfluxDBClient primary client object to connect InfluxDB.

The \texttt{InfluxDBClient} object holds information necessary to connect to InfluxDB. Requests can be made to InfluxDB directly through the client.

**Parameters**

- \texttt{host (str)} – hostname to connect to InfluxDB, defaults to 'localhost'
- \texttt{port (int)} – port to connect to InfluxDB, defaults to 8086
- \texttt{username (str)} – user to connect, defaults to 'root'
- \texttt{password (str)} – password of the user, defaults to 'root'
- \texttt{database (str)} – database name to connect to, defaults to None
- \texttt{ssl (bool)} – use https instead of http to connect to InfluxDB, defaults to False
- \texttt{verify\_ssl (bool)} – verify SSL certificates for HTTPS requests, defaults to False
- \texttt{timeout (int)} – number of seconds Requests will wait for your client to establish a connection, defaults to None
- \texttt{retries (int)} – number of retries your client will try before aborting, defaults to 3. 0 indicates try until success
- \texttt{use\_udp (bool)} – use UDP to connect to InfluxDB, defaults to False
- \texttt{udp\_port (int)} – UDP port to connect to InfluxDB, defaults to 4444
- \texttt{proxies (dict)} – HTTP(S) proxy to use for Requests, defaults to 

InfluxDB Documentation, Release 4.1.1

**alter_retention_policy** *(name, database=None, duration=None, replication=None, default=None)*

Modify an existing retention policy for a database.

**Parameters**

- **name** *(str)* – the name of the retention policy to modify
- **database** *(str)* – the database for which the retention policy is modified. Defaults to current client’s database
- **duration** *(str)* – the new duration of the existing retention policy. Durations such as 1h, 90m, 12h, 7d, and 4w, are all supported and mean 1 hour, 90 minutes, 12 hours, 7 day, and 4 weeks, respectively. For infinite retention, meaning the data will never be deleted, use ‘INF’ for duration. The minimum retention period is 1 hour.
- **replication** *(int)* – the new replication of the existing retention policy
- **default** *(bool)* – whether or not to set the modified policy as default

**Note:** at least one of duration, replication, or default flag should be set. Otherwise the operation will fail.

**close()**

Close http session.

**create_database** *(dbname)*

Create a new database in InfluxDB.

**Parameters**

- **dbname** *(str)* – the name of the database to create

**create_retention_policy** *(name, duration, replication, database=None, default=False)*

Create a retention policy for a database.

**Parameters**

- **name** *(str)* – the name of the new retention policy
- **duration** *(str)* – the duration of the new retention policy. Durations such as 1h, 90m, 12h, 7d, and 4w, are all supported and mean 1 hour, 90 minutes, 12 hours, 7 day, and 4 weeks, respectively. For infinite retention - meaning the data will never be deleted - use ‘INF’ for duration. The minimum retention period is 1 hour.
- **replication** *(str)* – the replication of the retention policy
- **database** *(str)* – the database for which the retention policy is created. Defaults to current client’s database
- **default** *(bool)* – whether or not to set the policy as default

**create_user** *(username, password, admin=False)*

Create a new user in InfluxDB.

**Parameters**

- **username** *(str)* – the new username to create
- **password** *(str)* – the password for the new user
- **admin** *(boolean)* – whether the user should have cluster administration privileges or not

**delete_series** *(database=None, measurement=None, tags=None)*

Delete series from a database.
Series can be filtered by measurement and tags.

Parameters

- **database** *(str)* – the database from which the series should be deleted, defaults to client’s current database
- **measurement** *(str)* – Delete all series from a measurement
- **tags** *(dict)* – Delete all series that match given tags

**drop_database** *(dbname)*

Drop a database from InfluxDB.

Parameters **dbname** *(str)* – the name of the database to drop

**drop_measurement** *(measurement)*

Drop a measurement from InfluxDB.

Parameters **measurement** *(str)* – the name of the measurement to drop

**drop_retention_policy** *(name, database=None)*

Drop an existing retention policy for a database.

Parameters

- **name** *(str)* – the name of the retention policy to drop
- **database** *(str)* – the database for which the retention policy is dropped. Defaults to current client’s database

**drop_user** *(username)*

Drop a user from InfluxDB.

Parameters **username** *(str)* – the username to drop

**classmethod from_dsn** *(dsn, **kwargs)*

Generate an instance of InfluxDBClient from given data source name.

Return an instance of **InfluxDBClient** from the provided data source name. Supported schemes are “influxdb”, “https+influxdb” and “udp+influxdb”. Parameters for the **InfluxDBClient** constructor may also be passed to this method.

Parameters

- **dsn** *(string)* – data source name
- **kwargs** *(dict)* – additional parameters for **InfluxDBClient**

Raises **ValueError** – if the provided DSN has any unexpected values

Example

```
>> cli = InfluxDBClient.from_dsn('influxdb://username:password@localhost:8086/databasename', timeout=5)
>> type(cli)
<class 'influxdb.client.InfluxDBClient'>
>> cli = InfluxDBClient.from_dsn('udp+influxdb://username:pass@localhost:8086/databasename', timeout=5, udp_port=159)
>> print('{0._baseurl} - {0.use_udp} {0.udp_port}'.format(cli))
http://localhost:8086 - True 159
```

**Note:** parameters provided in **kwargs may override dsn parameters
**Note:** when using “udp+influxdb” the specified port (if any) will be used for the TCP connection; specify the UDP port with the additional `udp_port` parameter (cf. examples).

`get_list_database()`  
Get the list of databases in InfluxDB.  

**Returns** all databases in InfluxDB  
**Return type** list of dictionaries  
**Example**

```python
>> dbs = client.get_list_database()
>> dbs
[{u'name': u'db1'}, {u'name': u'db2'}, {u'name': u'db3'}]
```

`get_list_measurements()`  
Get the list of measurements in InfluxDB.  

**Returns** all measurements in InfluxDB  
**Return type** list of dictionaries  
**Example**

```python
>> dbs = client.get_list_measurements()
>> dbs
[{u'name': u'measurements1'},
 {u'name': u'measurements2'},
 {u'name': u'measurements3'}]
```

`get_list_privileges(username)`  
Get the list of all privileges granted to given user.  

**Parameters** `username` *(str)* – the username to get privileges of  

**Returns** all privileges granted to given user  
**Return type** list of dictionaries  
**Example**

```python
>> privileges = client.get_list_privileges('user1')
>> privileges
[{u'privilege': u'WRITE', u'database': u'db1'},
 {u'privilege': u'ALL PRIVILEGES', u'database': u'db2'},
 {u'privilege': u'NO PRIVILEGES', u'database': u'db3'}]
```

`get_list_retention_policies(database=None)`  
Get the list of retention policies for a database.  

**Parameters** `database` *(str)* – the name of the database, defaults to the client’s current database  

**Returns** all retention policies for the database  
**Return type** list of dictionaries  
**Example**
get_list_retention_policies('my_db')
>> ret_policies
[[
    {u'default': True,
     u'duration': u'0',
     u'name': u'default',
     u'replicaN': 1}
]

get_list_users()
Get the list of all users in InfluxDB.

Returns all users in InfluxDB

Return type list of dictionaries

Example

>> users = client.get_list_users()
>> users
[[
    {u'admin': True, u'user': u'user1'},
     {u'admin': False, u'user': u'user2'},
     {u'admin': False, u'user': u'user3'}
]

grant_admin_privileges(username)
Grant cluster administration privileges to a user.

Parameters username (str) – the username to grant privileges to

Note: Only a cluster administrator can create/drop databases and manage users.

grant_privilege(privilege, database, username)
Grant a privilege on a database to a user.

Parameters

• privilege (str) – the privilege to grant, one of ‘read’, ‘write’ or ‘all’. The string is case-insensitive

• database (str) – the database to grant the privilege on

• username (str) – the username to grant the privilege to

query(query, params=None, epoch=None, expected_response_code=200, database=None, raise_errors=True, chunked=False, chunk_size=0)
Send a query to InfluxDB.

Parameters

• query (str) – the actual query string

• params (dict) – additional parameters for the request, defaults to {}

• epoch (str) – response timestamps to be in epoch format either ‘h’, ‘m’, ‘s’, ‘ms’, ‘u’, or ‘ns’. defaults to None which is RFC3339 UTC format with nanosecond precision

• expected_response_code (int) – the expected status code of response, defaults to 200

• database (str) – database to query, defaults to None

• raise_errors (bool) – Whether or not to raise exceptions when InfluxDB returns errors, defaults to True
• **chunked** *(bool)* – Enable to use chunked responses from InfluxDB. With chunked enabled, one ResultSet is returned per chunk containing all results within that chunk

• **chunk_size** *(int)* – Size of each chunk to tell InfluxDB to use.

Returns the queried data

Return type **ResultSet**

**request** *(url, method=u'GET', params=None, data=None, expected_response_code=200, headers=None)*

Make a HTTP request to the InfluxDB API.

Parameters

• **url** *(str)* – the path of the HTTP request, e.g. write, query, etc.

• **method** *(str)* – the HTTP method for the request, defaults to GET

• **params** *(dict)* – additional parameters for the request, defaults to None

• **data** *(str)* – the data of the request, defaults to None

• **expected_response_code** *(int)* – the expected response code of the request, defaults to 200

• **headers** *(dict)* – headers to add to the request

Returns the response from the request

Return type **requests.Response**

Raises

• **InfluxDBServerError** – if the response code is any server error code (5xx)

• **InfluxDBClientError** – if the response code is not the same as **expected_response_code** and is not a server error code

**revoke_admin_privileges** *(username)*

Revoke cluster administration privileges from a user.

Parameters **username** *(str)* – the username to revoke privileges from

---

**Note:** Only a cluster administrator can create/ drop databases and manage users.

**revoke_privilege** *(privilege, database, username)*

Revoke a privilege on a database from a user.

Parameters

• **privilege** *(str)* – the privilege to revoke, one of ‘read’, ‘write’ or ‘all’. The string is case-insensitive

• **database** *(str)* – the database to revoke the privilege on

• **username** *(str)* – the username to revoke the privilege from

**send_packet** *(packet, protocol=u'json')*

Send an UDP packet.

Parameters

• **packet** *(if protocol is 'json') dict (if protocol is 'line') sequence of line protocol strings* – the packet to be sent
- **protocol** *(str)* – protocol of input data, either ‘json’ or ‘line’

**set_user_password**(username, password)
Change the password of an existing user.

**Parameters**

- **username** *(str)* – the username who’s password is being changed
- **password** *(str)* – the new password for the user

**switch_database**(database)
Change the client’s database.

**Parameters**

- **database** *(str)* – the name of the database to switch to

**switch_user**(username, password)
Change the client’s username.

**Parameters**

- **username** *(str)* – the username to switch to
- **password** *(str)* – the password for the username

**write**(data, params=None, expected_response_code=204, protocol=u'json')
Write data to InfluxDB.

**Parameters**

- **data** – the data to be written
- **params** *(dict)* – additional parameters for the request, defaults to None
- **expected_response_code** *(int)* – the expected response code of the write operation, defaults to 204
- **protocol** *(str)* – protocol of input data, either ‘json’ or ‘line’

**Returns**

True, if the write operation is successful

**Return type**

bool

**write_points**(points, time_precision=None, database=None, retention_policy=None, tags=None, batch_size=None, protocol=u'json')
Write to multiple time series names.

**Parameters**

- **points** *(list of dictionaries, each dictionary represents a point)* – the list of points to be written in the database
- **time_precision** *(str)* – Either ‘s’, ‘m’, ‘ms’ or ‘u’, defaults to None
- **database** *(str)* – the database to write the points to. Defaults to the client’s current database
- **tags** *(dict)* – a set of key-value pairs associated with each point. Both keys and values must be strings. These are shared tags and will be merged with point-specific tags, defaults to None
- **retention_policy** *(str)* – the retention policy for the points. Defaults to None
- **batch_size** *(int)* – value to write the points in batches instead of all at one time. Useful for when doing data dumps from one database to another or when doing a massive write operation, defaults to None
- **protocol** *(str)* – Protocol for writing data. Either ‘line’ or ‘json’.
Returns True, if the operation is successful

Return type bool

Note: if no retention policy is specified, the default retention policy for the database is used

DataFrameClient

class influxdb.DataFrameClient(host=u'localhost', port=8086, username=u'root', password=u'root', database=None, ssl=False, verify_ssl=False, timeout=None, retries=3, use_udp=False, udp_port=4444, proxies=None)

DataFrameClient instantiates InfluxDBClient to connect to the backend.

The DataFrameClient object holds information necessary to connect to InfluxDB. Requests can be made to InfluxDB directly through the client. The client reads and writes from pandas DataFrames.

EPOCH = Timestamp('1970-01-01 00:00:00+0000', tz='UTC')

query(query, params=None, epoch=None, expected_response_code=200, database=None, raise_errors=True, chunked=False, chunk_size=0, dropna=True)

Quering data into a DataFrame.

Parameters

• query – the actual query string

• params – additional parameters for the request, defaults to {}

• epoch – response timestamps to be in epoch format either ‘h’, ‘m’, ‘s’, ‘ms’, ‘u’, or ‘ns’. defaults to None which is RFC3339 UTC format with nanosecond precision

• expected_response_code – the expected status code of response, defaults to 200

• database – database to query, defaults to None

• raise_errors – Whether or not to raise exceptions when InfluxDB returns errors, defaults to True

• chunked – Enable to use chunked responses from InfluxDB. With chunked enabled, one ResultSet is returned per chunk containing all results within that chunk

• chunk_size – Size of each chunk to tell InfluxDB to use.

• dropna – drop columns where all values are missing

Returns the queried data

Return type ResultSet

write_points(dataframe, measurement, tags=None, tag_columns=None, field_columns=None, time_precision=None, database=None, retention_policy=None, batch_size=None, protocol=u'line', numeric_precision=None)

Write to multiple time series names.

Parameters

• dataframe – data points in a DataFrame

• measurement – name of measurement

• tags – dictionary of tags, with string key-values

1.2. API Documentation
• **time_precision** – [Optional, default None] Either ‘s’, ‘ms’, ‘u’ or ‘n’.

• **batch_size**(int) – [Optional] Value to write the points in batches instead of all at one time. Useful for when doing data dumps from one database to another or when doing a massive write operation

• **protocol** – Protocol for writing data. Either ‘line’ or ‘json’.

• **numeric_precision** – Precision for floating point values. Either None, ‘full’ or some int, where int is the desired decimal precision. ‘full’ preserves full precision for int and float datatypes. Defaults to None, which preserves 14-15 significant figures for float and all significant figures for int datatypes.

### SeriesHelper

class influxdb.SeriesHelper(**kw)

Subclass this helper eases writing data points in bulk.

All data points are immutable, ensuring they do not get overwritten. Each subclass can write to its own database. The time series names can also be based on one or more defined fields. The field “time” can be specified when creating a point, and may be any of the time types supported by the client (i.e. str, datetime, int). If the time is not specified, the current system time (utc) will be used.

Annotated example:

```python
class MySeriesHelper(SeriesHelper):
    class Meta:
        # Meta class stores time series helper configuration.
        series_name = 'events.stats.{server_name}'
        # Series name must be a string, curly brackets for dynamic use.
        fields = ['time', 'server_name']
        # Defines all the fields in this time series.
        ### Following attributes are optional. ###
        client = TestSeriesHelper.client
        # Client should be an instance of InfluxDBClient.
        :warning: Only used if autocommit is True.
        bulk_size = 5
        # Defines the number of data points to write simultaneously.
        # Only applicable if autocommit is True.
        autocommit = True
        # If True and no bulk_size, then will set bulk_size to 1.

    @classmethod
    def commit(cls, client=None)
        Commit everything from datapoints via the client.

        Parameters client – InfluxDBClient instance for writing points to InfluxDB.

        Attention any provided client will supersede the class client.

        Returns result of client.write_points.
```

### ResultSet

See the *Query response object: ResultSet* page for more information.

class influxdb.resultset.ResultSet(s series, raise_errors=True)

A wrapper around a single InfluxDB query result.
error
Error returned by InfluxDB.

get_points(measurement=None, tags=None)
Return a generator for all the points that match the given filters.

Parameters
• measurement(str) – The measurement name
• tags(dict) – Tags to look for

Returns Points generator

items()
Return the set of items from the ResultSet.

Returns List of tuples, (key, generator)

keys()
Return the list of keys in the ResultSet.

Returns List of keys. Keys are tuples (serie_name, tags)

static point_from_cols_vals(cols, vals)
Create a dict from columns and values lists.

Parameters
• cols – List of columns
• vals – List of values

Returns Dict where keys are columns.

raw
Raw JSON from InfluxDB.

Exceptions

class influxdb.exceptions.InfluxDBClientError(content, code=None)
Raised when an error occurs in the request.

class influxdb.exceptions.InfluxDBServerError(content)
Raised when a server error occurs.

Query response object: ResultSet

Using the InfluxDBClient.query() function will return a ResultSet Object.

A ResultSet can be browsed in several ways. Its get_points method can be used to retrieve points generators that filter either by measurement, tags, or both.

Getting all points

Using rs.get_points() will return a generator for all the points in the ResultSet.
Filtering by measurement

Using `rs.get_points('cpu')` will return a generator for all the points that are in a serie with measurement name `cpu`, no matter the tags.

```python
rs = cli.query("SELECT * from cpu")
cpu_points = list(rs.get_points(measurement='cpu'))
```

Filtering by tags

Using `rs.get_points(tags={'host_name': 'influxdb.com'})` will return a generator for all the points that are tagged with the specified tags, no matter the measurement name.

```python
rs = cli.query("SELECT * from cpu")
cpu_influxdb_com_points = list(rs.get_points(tags={'host_name': "influxdb.com"}))
```

Filtering by measurement and tags

Using measurement name and tags will return a generator for all the points that are in a serie with the specified measurement name AND whose tags match the given tags.

```python
rs = cli.query("SELECT * from cpu")
points = list(rs.get_points(measurement='cpu', tags={'host_name': 'influxdb.com'}))
```

See the API Documentation page for more information.

InfluxDB Python Examples

Tutorials - Basic

```python
# -*- coding: utf-8 -*-

"""Tutorial on using the InfluxDB client."""

import argparse

from influxdb import InfluxDBClient

def main(host='localhost', port=8086):
    """Instantiate a connection to the InfluxDB."""
    user = 'root'
    password = 'root'
    dbname = 'example'
    dbuser = 'smly'
    dbuser_password = 'my_secret_password'
    query = 'select value from cpu_load_short;
    json_body = [
        {
            "measurement": "cpu_load_short",
            "tags": {
                "host": "server01",
                "region": "us-west"}}]"""
```
```python
client = InfluxDBClient(host, port, user, password, dbname)

print("Create database: " + dbname)
client.create_database(dbname)

print("Create a retention policy")
client.create_retention_policy('awesome_policy', '3d', 3, default=True)

print("Switch user: " + dbuser)
