- What’s new
psutil (python system and process utilities) is a cross-platform library for retrieving information on running processes and system utilization (CPU, memory, disks, network, sensors) in Python. It is useful mainly for system monitoring, profiling, limiting process resources and the management of running processes. It implements many functionalities offered by UNIX command line tools such as: ps, top, lsof, netstat, ifconfig, who, df, kill, free, nice, ionice, iostat, iotop, uptime, pidof, tty, taskset, pmap. psutil currently supports the following platforms:

- Linux
- Windows
- macOS
- FreeBSD, OpenBSD, NetBSD
- Sun Solaris
- AIX

...both 32-bit and 64-bit architectures. Supported Python versions are 2.6, 2.7 and 3.4+. PyPy is also known to work.

The psutil documentation you’re reading is distributed as a single HTML page.
The easiest way to install psutil is via pip:

```
pip install psutil
```

On UNIX this requires a C compiler (e.g. gcc) installed. On Windows pip will automatically retrieve a pre-compiled wheel version from PyPI repository. Alternatively, see more detailed install instructions.
CHAPTER 4

System related functions

4.1 CPU

psutil.cpu_times(percpu=False)

Return system CPU times as a named tuple. Every attribute represents the seconds the CPU has spent in the
given mode. The attributes availability varies depending on the platform:

- **user**: time spent by normal processes executing in user mode; on Linux this also includes **guest** time
- **system**: time spent by processes executing in kernel mode
- **idle**: time spent doing nothing

Platform-specific fields:

- **nice** (*UNIX*): time spent by niced (prioritized) processes executing in user mode; on Linux this also in-
  cludes **guest_nice** time
- **iowait** (*Linux*): time spent waiting for I/O to complete
- **irq** (*Linux, BSD*): time spent for servicing hardware interrupts
- **softirq** (*Linux*): time spent for servicing software interrupts
- **steal** (*Linux 2.6.11+*): time spent by other operating systems running in a virtualized environment
- **guest** (*Linux 2.6.24+*): time spent running a virtual CPU for guest operating systems under the control of
  the Linux kernel
- **guest_nice** (*Linux 3.2.0+*): time spent running a niced guest (virtual CPU for guest operating systems
  under the control of the Linux kernel)
- **interrupt** (*Windows*): time spent for servicing hardware interrupts (similar to “irq” on UNIX)
- **dpc** (*Windows*): time spent servicing deferred procedure calls (DPCs); DPCs are interrupts that run at a
  lower priority than standard interrupts.
When `percpu` is `True` return a list of named tuples for each logical CPU on the system. First element of the list refers to first CPU, second element to second CPU and so on. The order of the list is consistent across calls. Example output on Linux:

```python
>>> import psutil
>>> psutil.cpu_times()
sctimes(user=17411.7, nice=77.99, system=3797.02, idle=51266.57, iowait=732.58, IRQ=0.01, softirq=142.43, steal=0.0, guest=0.0, guest_nice=0.0)
```

Changed in version 4.1.0: added `interrupt` and `dpc` fields on Windows.

`psutil.cpu_percent(interval=None, percpu=False)`

Return a float representing the current system-wide CPU utilization as a percentage. When `interval` is > 0.0 compares system CPU times elapsed before and after the interval (blocking). When `interval` is 0.0 or `None` compares system CPU times elapsed since last call or module import, returning immediately. That means the first time this is called it will return a meaningless 0.0 value which you are supposed to ignore. In this case it is recommended for accuracy that this function be called with at least 0.1 seconds between calls. When `percpu` is `True` returns a list of floats representing the utilization as a percentage for each CPU. First element of the list refers to first CPU, second element to second CPU and so on. The order of the list is consistent across calls.

```python
>>> import psutil
>>> # blocking
>>> psutil.cpu_percent(interval=1)
2.0
>>> # non-blocking (percentage since last call)
>>> psutil.cpu_percent(interval=None)
2.9
>>> # blocking, per-cpu
>>> psutil.cpu_percent(interval=1, percpu=True)
[2.0, 1.0]
```

**Warning:** the first time this function is called with `interval = 0.0` or `None` it will return a meaningless 0.0 value which you are supposed to ignore.

`psutil.cpu_times_percent(interval=None, percpu=False)`

Same as `cpu_percent()` but provides utilization percentages for each specific CPU time as is returned by `psutil.cpu_times(percpu=True)`. `interval` and `percpu` arguments have the same meaning as in `cpu_percent()`. On Linux “guest” and “guest_nice” percentages are not accounted in “user” and “user_nice” percentages.

**Warning:** the first time this function is called with `interval = 0.0` or `None` it will return a meaningless 0.0 value which you are supposed to ignore.

Changed in version 4.1.0: two new `interrupt` and `dpc` fields are returned on Windows.

`psutil.cpu_count(logical=True)`

Return the number of logical CPUs in the system (same as `os.cpu_count()` in Python 3.4) or None if undetermined. If `logical` is `False` return the number of physical cores only (hyper thread CPUs are excluded) or `None` if undetermined. On OpenBSD and NetBSD `psutil.cpu_count(logical=False)` always return `None`. Example on a system having 2 physical hyper-thread CPU cores:
>>> import psutil
>>> psutil.cpu_count()
4
>>> psutil.cpu_count(logical=False)
2

Note that this number is not equivalent to the number of CPUs the current process can actually use. That can vary in case process CPU affinity has been changed, Linux cgroups are being used or on Windows systems using processor groups or having more than 64 CPUs. The number of usable CPUs can be obtained with:

>>> len(psutil.Process().cpu_affinity())
1

\texttt{psutil.cpu_stats}()

Return various CPU statistics as a named tuple:

- \texttt{ctx\_switches}: number of context switches (voluntary + involuntary) since boot.
- \texttt{interrupts}: number of interrupts since boot.
- \texttt{soft\_interrupts}: number of software interrupts since boot. Always set to 0 on Windows and SunOS.
- \texttt{syscalls}: number of system calls since boot. Always set to 0 on Linux.

Example (Linux):

```python
>>> import psutil
>>> psutil.cpu_stats()
scpustats(ctx_switches=20455687, interrupts=6598984, soft_interrupts=2134212, \rightarrow syscalls=0)
```

New in version 4.1.0.

\texttt{psutil.cpu_freq} (\texttt{percpu=False})

Return CPU frequency as a named tuple including \texttt{current}, \texttt{min} and \texttt{max} frequencies expressed in Mhz. On Linux \texttt{current} frequency reports the real-time value, on all other platforms it represents the nominal “fixed” value. If \texttt{percpu} is \texttt{True} and the system supports per-cpu frequency retrieval (Linux only) a list of frequencies is returned for each CPU, if not, a list with a single element is returned. If \texttt{min} and \texttt{max} cannot be determined they are set to 0.

Example (Linux):

```python
>>> import psutil
>>> psutil.cpu_freq()
scpufreq(current=931.42925, min=800.0, max=3500.0)
>>> psutil.cpu_freq(percpu=True)
[scpufreq(current=2394.945, min=800.0, max=3500.0),
 scpufreq(current=2236.812, min=800.0, max=3500.0),
 scpufreq(current=1703.609, min=800.0, max=3500.0),
 scpufreq(current=1754.289, min=800.0, max=3500.0)]
```

Availability: Linux, macOS, Windows, FreeBSD

New in version 5.1.0.

Changed in version 5.5.1: added FreeBSD support.
4.2 Memory

psutil.virtual_memory()
Return statistics about system memory usage as a named tuple including the following fields, expressed in bytes.
Main metrics:

- **total**: total physical memory.
- **available**: the memory that can be given instantly to processes without the system going into swap. This is calculated by summing different memory values depending on the platform and it is supposed to be used to monitor actual memory usage in a cross platform fashion.

Other metrics:

- **used**: memory used, calculated differently depending on the platform and designed for informational purposes only. **total - free** does not necessarily match **used**.
- **free**: memory not being used at all (zeroed) that is readily available; note that this doesn’t reflect the actual memory available (use **available** instead). **total - used** does not necessarily match **free**.
- **active** (UNIX): memory currently in use or very recently used, and so it is in RAM.
- **inactive** (UNIX): memory that is marked as not used.
- **buffers** (Linux, BSD): cache for things like file system metadata.
- **cached** (Linux, BSD): cache for various things.
- **shared** (Linux, BSD): memory that may be simultaneously accessed by multiple processes.
- **slab** (Linux): in-kernel data structures cache.
- **wired** (BSD, macOS): memory that is marked to always stay in RAM. It is never moved to disk.

The sum of **used** and **available** does not necessarily equal **total**. On Windows **available** and **free** are the same. See meminfo.py script providing an example on how to convert bytes in a human readable form.

Note: if you just want to know how much physical memory is left in a cross platform fashion simply rely on the **available** field.

```
>>> import psutil
>>> mem = psutil.virtual_memory()
>>> mem
svmem(total=10367352832, available=6472179712, percent=37.6, used=8186245120, ...
→free=2181107712, active=4748992512, inactive=2758115328, buffers=790724608, ...
→cached=3500347392, shared=787554304, slab=199348224)
>>> THRESHOLD = 100 * 1024 * 1024  # 100MB
>>> if mem.available <= THRESHOLD:
...     print("warning")
...     ...
>>>```

Changed in version 4.2.0: added **shared** metric on Linux.

Changed in version 5.4.4: added **slab** metric on Linux.

psutil.swap_memory()
Return system swap memory statistics as a named tuple including the following fields:

- **total**: total swap memory in bytes
• **used**: used swap memory in bytes
• **free**: free swap memory in bytes
• **percent**: the percentage usage calculated as \((total - available) / total \times 100\)
• **sin**: the number of bytes the system has swapped in from disk (cumulative)
• **sout**: the number of bytes the system has swapped out from disk (cumulative)

**sin** and **sout** on Windows are always set to 0. See `meminfo.py` script providing an example on how to convert bytes in a human readable form.

```python
>>> import psutil

>>> psutil.swap_memory()
sswap(total=2097147904L, used=886620160L, free=1210527744L, percent=42.3, ...
    sin=1050411008, sout=1906720768)
```

Changed in version 5.2.3: on Linux this function relies on `/proc` fs instead of `sysinfo()` syscall so that it can be used in conjunction with `psutil.PROCFS_PATH` in order to retrieve memory info about Linux containers such as Docker and Heroku.

### 4.3 Disks

**psutil.disk_partitions**(all=False)

Return all mounted disk partitions as a list of named tuples including device, mount point and filesystem type, similarly to the “df” command on UNIX. If all parameter is False it tries to distinguish and return physical devices only (e.g. hard disks, cd-rom drives, USB keys) and ignore all others (e.g. memory partitions such as `/dev/shm`). Note that this may not be fully reliable on all systems (e.g. on BSD this parameter is ignored). Named tuple’s `fstype` field is a string which varies depending on the platform. On Linux it can be one of the values found in `/proc/filesystems` (e.g. `'ext3'` for an ext3 hard drive or `'iso9660'` for the CD-ROM drive). On Windows it is determined via `GetDriveType` and can be either `'removable'`, `'fixed'`, `'remote'`, `'cdrom'`, `'unmounted'` or `'ramdisk'`. On macOS and BSD it is retrieved via `getfsstat(2)`. See `disk_usage.py` script providing an example usage.

```python
>>> import psutil

>>> psutil.disk_partitions()
[sdiskpart(device='/dev/sda3', mountpoint='/', fstype='ext4', opts='rw, ...
    errors=remount-ro'),
    sdiskpart(device='/dev/sda7', mountpoint='/home', fstype='ext4', opts='rw')]
```

**psutil.disk_usage**(path)

Return disk usage statistics about the partition which contains the given path as a named tuple including total, used and free space expressed in bytes, plus the percentage usage. `OSError` is raised if path does not exist. Starting from Python 3.3 this is also available as `shutil.disk_usage()`. See `disk_usage.py` script providing an example usage.

```python
>>> import psutil

>>> psutil.disk_usage('/')
sdiskusage(total=21378641920, used=4809781248, free=15482871808, percent=22.5)
```

**Note**: UNIX usually reserves 5% of the total disk space for the root user. **total** and **used** fields on UNIX refer to the overall total and used space, whereas **free** represents the space available for the **user** and **percent** represents the **user** utilization (see source code). That is why **percent** value may look 5% bigger than what you would expect it to be. Also note that both 4 values match “df” cmdline utility.
psutil Documentation, Release 5.5.0

Changed in version 4.3.0: percent value takes root reserved space into account.

\texttt{psutil.disk_io_counters} (perdisk=False, nowrap=True)

Return system-wide disk I/O statistics as a named tuple including the following fields:

- \texttt{read_count}: number of reads
- \texttt{write_count}: number of writes
- \texttt{read_bytes}: number of bytes read
- \texttt{write_bytes}: number of bytes written

Platform-specific fields:

- \texttt{read_time}: (all except NetBSD and OpenBSD) time spent reading from disk (in milliseconds)
- \texttt{write_time}: (all except NetBSD and OpenBSD) time spent writing to disk (in milliseconds)
- \texttt{busy_time}: (Linux, FreeBSD) time spent doing actual I/Os (in milliseconds)
- \texttt{read_merged_count} (Linux): number of merged reads (see iostat doc)
- \texttt{write_merged_count} (Linux): number of merged writes (see iostats doc)

If \texttt{perdisk} is True return the same information for every physical disk installed on the system as a dictionary with partition names as the keys and the named tuple described above as the values. See \texttt{iotop.py} for an example application. On some systems such as Linux, on a very busy or long-lived system, the numbers returned by the kernel may overflow and wrap (restart from zero). If \texttt{nowrap} is True psutil will detect and adjust those numbers across function calls and add “old value” to “new value” so that the returned numbers will always be increasing or remain the same, but never decrease. \texttt{disk_io_counters.cache\_clear()} can be used to invalidate the \texttt{nowrap} cache. On Windows it may be necessary to issue diskperf -y command from cmd.exe first in order to enable IO counters. On diskless machines this function will return None or {} if \texttt{perdisk} is True.

```python
>>> import psutil

>>> psutil.disk_io_counters()

diskio(read_count=8141, write_count=2431, read_bytes=290203, write_bytes=537676, read_time=5868, write_time=94922)

>>> psutil.disk_io_counters(perdisk=True)

{'sda1': diskio(read_count=920, write_count=1, read_bytes=2933248, write_bytes=512, read_time=6016, write_time=4),
 'sda2': diskio(read_count=18707, write_count=8830, read_bytes=6060, write_bytes=3443, read_time=24585, write_time=1572),
 'sdb1': diskio(read_count=161, write_count=0, read_bytes=786432, write_bytes=0, read_time=44, write_time=0)}
```

\textbf{Note}: on Windows "diskperf -y" command may need to be executed first otherwise this function won’t find any disk.

Changed in version 5.3.0: numbers no longer wrap (restart from zero) across calls thanks to new \texttt{nowrap} argument.

Changed in version 4.0.0: added \texttt{busy\_time} (Linux, FreeBSD), \texttt{read\_merged\_count} and \texttt{write\_merged\_count} (Linux) fields.

Changed in version 4.0.0: NetBSD no longer has \texttt{read\_time} and \texttt{write\_time} fields.
4.4 Network

**psutil.net_io_counters**(pernic=False, nowrap=True)

Return system-wide network I/O statistics as a named tuple including the following attributes:

- **bytes_sent**: number of bytes sent
- **bytes_recv**: number of bytes received
- **packets_sent**: number of packets sent
- **packets_recv**: number of packets received
- **errin**: total number of errors while receiving
- **errout**: total number of errors while sending
- **dropin**: total number of incoming packets which were dropped
- **dropout**: total number of outgoing packets which were dropped (always 0 on macOS and BSD)

If `pernic` is True return the same information for every network interface installed on the system as a dictionary with network interface names as the keys and the named tuple described above as the values. On some systems such as Linux, on a very busy or long-lived system, the numbers returned by the kernel may overflow and wrap (restart from zero). If `nowrap` is True psutil will detect and adjust those numbers across function calls and add “old value” to “new value” so that the returned numbers will always be increasing or remain the same, but never decrease. `net_io_counters.cache_clear()` can be used to invalidate the `nowrap` cache. On machines with no network interfaces this function will return None or {} if `pernic` is True.

```python
>>> import psutil
>>> psutil.net_io_counters()
snetio(bytes_sent=14508483, bytes_recv=62749361, packets_sent=84311, packets_recv=94888, errin=0, errout=0, dropin=0, dropout=0)
>>> psutil.net_io_counters(pernic=True)
{'lo': snetio(bytes_sent=547971, bytes_recv=547971, packets_sent=5075, packets_recv=5075, errin=0, errout=0, dropin=0, dropout=0),
 'wlan0': snetio(bytes_sent=13921765, bytes_recv=62162574, packets_sent=79097, packets_recv=89648, errin=0, errout=0, dropin=0, dropout=0)}
```

Also see nettop.py and ifconfig.py for an example application.

Changed in version 5.3.0: numbers no longer wrap (restart from zero) across calls thanks to new nowrap argument.

**psutil.net_connections**(kind=’inet’)

Return system-wide socket connections as a list of named tuples. Every named tuple provides 7 attributes:

- **fd**: the socket file descriptor. If the connection refers to the current process this may be passed to `socket.fromfd()` to obtain a usable socket object. On Windows and SunOS this is always set to -1.
- **family**: the address family, either AF_INET, AF_INET6 or AF_UNIX.
- **type**: the address type, either SOCK_STREAM or SOCK_DGRAM.
- **laddr**: the local address as a (ip, port) named tuple or a path in case of AF_UNIX sockets. For UNIX sockets see notes below.
- **raddr**: the remote address as a (ip, port) named tuple or an absolute path in case of UNIX sockets. When the remote endpoint is not connected you’ll get an empty tuple (AF_INET*) or "" (AF_UNIX). For UNIX sockets see notes below.
• **status**: represents the status of a TCP connection. The return value is one of the `psutil.CONN_*` constants (a string). For UDP and UNIX sockets this is always going to be `psutil.CONN_NONE`.

• **pid**: the PID of the process which opened the socket, if retrievable, else `None`. On some platforms (e.g. Linux) the availability of this field changes depending on process privileges (root is needed).

The `kind` parameter is a string which filters for connections matching the following criteria:

<table>
<thead>
<tr>
<th>Kind value</th>
<th>Connections using</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;inet&quot;</td>
<td>IPv4 and IPv6</td>
</tr>
<tr>
<td>&quot;inet4&quot;</td>
<td>IPv4</td>
</tr>
<tr>
<td>&quot;inet6&quot;</td>
<td>IPv6</td>
</tr>
<tr>
<td>&quot;tcp&quot;</td>
<td>TCP</td>
</tr>
<tr>
<td>&quot;tcp4&quot;</td>
<td>TCP over IPv4</td>
</tr>
<tr>
<td>&quot;tcp6&quot;</td>
<td>TCP over IPv6</td>
</tr>
<tr>
<td>&quot;udp&quot;</td>
<td>UDP</td>
</tr>
<tr>
<td>&quot;udp4&quot;</td>
<td>UDP over IPv4</td>
</tr>
<tr>
<td>&quot;udp6&quot;</td>
<td>UDP over IPv6</td>
</tr>
<tr>
<td>&quot;unix&quot;</td>
<td>UNIX socket (both UDP and TCP protocols)</td>
</tr>
<tr>
<td>&quot;all&quot;</td>
<td>the sum of all the possible families and protocols</td>
</tr>
</tbody>
</table>

On macOS and AIX this function requires root privileges. To get per-process connections use `Process.connections()`. Also, see `netstat.py` sample script. Example:

```python
>>> import psutil
>>> psutil.net_connections()
[pconn(fd=115, family=<AddressFamily.AF_INET: 2>, type=<SocketType.SOCK_STREAM: 1>,…
   laddr=addr(ip='10.0.0.1', port=48776), raddr=addr(ip='93.186.135.91',…
   port=80), status='ESTABLISHED', pid=1254),
pconn(fd=117, family=<AddressFamily.AF_INET: 2>, type=<SocketType.SOCK_STREAM: 1>,…
   laddr=addr(ip='10.0.0.1', port=43761), raddr=addr(ip='72.14.234.100',…
   port=80), status='CLOSING', pid=2987),
pconn(fd=-1, family=<AddressFamily.AF_INET: 2>, type=<SocketType.SOCK_STREAM: 1>,…
   laddr=addr(ip='10.0.0.1', port=60759), raddr=addr(ip='72.14.234.104', port=80),…
   status='ESTABLISHED', pid=None),
pconn(fd=-1, family=<AddressFamily.AF_INET: 2>, type=<SocketType.SOCK_STREAM: 1>,…
   laddr=addr(ip='10.0.0.1', port=51314), raddr=addr(ip='72.14.234.83', port=443),…
   status='SYN_SENT', pid=None)
...]
```

**Note**: (macOS and AIX) `psutil.AccessDenied` is always raised unless running as root. This is a limitation of the OS and `ls/of` does the same.

**Note**: (Solaris) UNIX sockets are not supported.

**Note**: (Linux, FreeBSD) “raddr” field for UNIX sockets is always set to “”. This is a limitation of the OS.

**Note**: (OpenBSD) “laddr” and “raddr” fields for UNIX sockets are always set to “”. This is a limitation of the OS.
psutil Documentation, Release 5.5.0

New in version 2.1.0.

Changed in version 5.3.0: `socket "fd"` is now set for real instead of being -1.

Changed in version 5.3.0: `"laddr"` and `"raddr"` are named tuples.

**psutil.net_if_addrs()**

Return the addresses associated to each NIC (network interface card) installed on the system as a dictionary whose keys are the NIC names and value is a list of named tuples for each address assigned to the NIC. Each named tuple includes 5 fields:

- **family**: the address family, either `AF_INET`, `AF_INET6` or `psutil.AF_LINK`, which refers to a MAC address.
- **address**: the primary NIC address (always set).
- **netmask**: the netmask address (may be `None`).
- **broadcast**: the broadcast address (may be `None`).
- **ptp**: stands for “point to point”; it’s the destination address on a point to point interface (typically a VPN). `broadcast` and `ptp` are mutually exclusive. May be `None`.

Example:

```python
>>> import psutil
>>> psutil.net_if_addrs()
{'lo': [snicaddr(family=<AddressFamily.AF_INET: 2>, address='127.0.0.1', netmask='255.0.0.0', broadcast='127.0.0.1', ptp=None),
         snicaddr(family=<AddressFamily.AF_INET6: 10>, address='::1', netmask='ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff', broadcast=None, ptp=None),
         snicaddr(family=<AddressFamily.AF_LINK: 17>, address='00:00:00:00:00:00', netmask=None, broadcast='00:00:00:00:00:00', ptp=None)],
'wlan0': [snicaddr(family=<AddressFamily.AF_INET: 2>, address='192.168.1.3', netmask='255.255.255.0', broadcast='192.168.1.255', ptp=None),
          snicaddr(family=<AddressFamily.AF_INET6: 10>, address='fe80::c685:8ff:fe45:641%wlan0', netmask='ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff', broadcast=None, ptp=None),
          snicaddr(family=<AddressFamily.AF_LINK: 17>, address='c4:85:08:45:06:41', netmask=None, broadcast='ff:ff:ff:ff:ff:ff', ptp=None)]}
```
psutil.net_if_stats()

Return information about each NIC (network interface card) installed on the system as a dictionary whose keys
are the NIC names and value is a named tuple with the following fields:

- `isup`: a bool indicating whether the NIC is up and running.
- `duplex`: the duplex communication type; it can be either `NIC_DUPLEX_FULL, NIC_DUPLEX_HALF` or 
  `NIC_DUPLEX UNKNOWN`.
- `speed`: the NIC speed expressed in mega bits (MB), if it can’t be determined (e.g. ‘localhost’) it will be 
  set to 0.
- `mtu`: NIC’s maximum transmission unit expressed in bytes.

Example:

```
>>> import psutil
>>> psutil.net_if_stats()
{'eth0': snicstats(isup=True, duplex=<NicDuplex.NIC_DUPLEX_FULL: 2>, speed=100,
  mtu=1500),
 'lo': snicstats(isup=True, duplex=<NicDuplex.NIC_DUPLEX_UNKNOWN: 0>, speed=0,
  mtu=65536)}
```

Also see nettop.py and ifconfig.py for an example application.

New in version 3.0.0.

4.5 Sensors

psutil.sensors_temperatures (fahrenheit=False)

Return hardware temperatures. Each entry is a named tuple representing a certain hardware temperature sensor 
(it may be a CPU, an hard disk or something else, depending on the OS and its configuration). All temperatures 
are expressed in celsius unless `fahrenheit` is set to `True`. If sensors are not supported by the OS an empty dict is returned. Example:

```
>>> import psutil
>>> psutil.sensors_temperatures()
{'acpitz': [shwtemp(label='', current=47.0, high=103.0, critical=103.0)], 
 'asus': [shwtemp(label='', current=47.0, high=None, critical=None)], 
 'coretemp': [shwtemp(label='Physical id 0', current=52.0, high=100.0, 
    critical=100.0),
    shwtemp(label='Core 0', current=45.0, high=100.0, critical=100.0),
    shwtemp(label='Core 1', current=52.0, high=100.0, critical=100.0),
    shwtemp(label='Core 2', current=45.0, high=100.0, critical=100.0),
    shwtemp(label='Core 3', current=47.0, high=100.0, critical=100.0)]}
```

See also temperatures.py and sensors.py for an example application.

Availability: Linux, FreeBSD

New in version 5.1.0.

Changed in version 5.5.0: added FreeBSD support

psutil.sensors_fans()

Return hardware fans speed. Each entry is a named tuple representing a certain hardware sensor fan. Fan speed is expressed in RPM (rounds per minute). If sensors are not supported by the OS an empty dict is returned. Example:
>>> import psutil
>>> psutil.sensors_fans()
{'asus': [sfan(label='cpu_fan', current=3200)]}

See also fans.py and sensors.py for an example application.
Availability: Linux, macOS
New in version 5.2.0.

psutil.sensors_battery()  
Return battery status information as a named tuple including the following values. If no battery is installed or metrics can’t be determined None is returned.

- **percent**: battery power left as a percentage.
- **secsleft**: a rough approximation of how many seconds are left before the battery runs out of power. If the AC power cable is connected this is set to `psutil.POWER_TIME_UNLIMITED`. If it can’t be determined it is set to `psutil.POWER_TIME_UNKNOWN`.
- **power_plugged**: True if the AC power cable is connected, False if not or None if it can’t be determined.

Example:

```python
>>> import psutil
>>> def secs2hours(secs):
...     mm, ss = divmod(secs, 60)
...     hh, mm = divmod(mm, 60)
...     return "%d:%02d:%02d" % (hh, mm, ss)
... >>>
>>> battery = psutil.sensors_battery()
>>> battery
sbattery(percent=93, secsleft=16628, power_plugged=False)
>>> print("charge = \$s\$, time left = \$s" % (battery.percent, secs2hours(battery.
˓→secsleft)))
charge = 93%, time left = 4:37:08
```

See also battery.py and sensors.py for an example application.

Availability: Linux, Windows, FreeBSD
New in version 5.1.0.
Changed in version 5.4.2: added macOS support

### 4.6 Other system info

psutil.boot_time()  
Return the system boot time expressed in seconds since the epoch. Example:

```python
>>> import psutil, datetime
>>> psutil.boot_time()
13889563460.0
>>> datetime.datetime.fromtimestamp(psutil.boot_time()).strftime("%Y-%m-%d %H:%M:%S")
'2014-01-12 22:51:00'
```
psutil Documentation, Release 5.5.0

Note: on Windows this function may return a time which is off by 1 second if it’s used across different processes (see issue #1007).

psutil.users()

Return users currently connected on the system as a list of named tuples including the following fields:

- **user**: the name of the user.
- **terminal**: the tty or pseudo-tty associated with the user, if any, else None.
- **host**: the host name associated with the entry, if any.
- **started**: the creation time as a floating point number expressed in seconds since the epoch.
- **pid**: the PID of the login process (like sshd, tmux, gdm-session-worker, ...). On Windows and OpenBSD this is always set to None.

Example:

```python
>>> import psutil
>>> psutil.users()
[(suser(name='giampaolo', terminal='pts/2', host='localhost', started=1340737536.0, pid=1352),
  suser(name='giampaolo', terminal='pts/3', host='localhost', started=1340737792.0, pid=1788)]
```

Changed in version 5.3.0: added “pid” field
5.1 Functions

`psutil.pids()`
Return a list of current running PIDs. To iterate over all processes and avoid race conditions
`process_iter()` should be preferred.

```python
>>> import psutil
>>> psutil.pids()
[1, 2, 3, 5, 7, 8, 9, 10, 11, 12, 13, 14, 15, 17, 18, 19, ..., 32498]
```

`psutil.process_iter(attrs=None, ad_value=None)`
Return an iterator yielding a `Process` class instance for all running processes on the local machine. Every instance is only created once and then cached into an internal table which is updated every time an element is yielded. Cached `Process` instances are checked for identity so that you’re safe in case a PID has been reused by another process, in which case the cached instance is updated. This is preferred over `psutil.pids()` for iterating over processes. Sorting order in which processes are returned is based on their PID. `attrs` and `ad_value` have the same meaning as in `Process.as_dict()`. If `attrs` is specified `Process.as_dict()` is called internally and the resulting dict is stored as an `info` attribute which is attached to the returned `Process` instances. If `attrs` is an empty list it will retrieve all process info (slow). Example usage:

```python
>>> import psutil
>>> for proc in psutil.process_iter():
...    try:
...        pinfo = proc.as_dict(attrs=['pid', 'name', 'username'])
...    except psutil.NoSuchProcess:
...        pass
...    else:
...        print(pinfo)
...    ...
{'name': 'systemd', 'pid': 1, 'username': 'root'}
{'name': 'kthreadd', 'pid': 2, 'username': 'root'}
{'name': 'ksoftirqd/0', 'pid': 3, 'username': 'root'}
```
More compact version using \textit{attrs} parameter:

```python
>>> import psutil
>>> for proc in psutil.process_iter(attrs=['pid', 'name', 'username']):
...     print(proc.info)
... [{'name': 'systemd', 'pid': 1, 'username': 'root'},
 'name': 'kthreadd', 'pid': 2, 'username': 'root'},
 {'name': 'ksoftirqd/0', 'pid': 3, 'username': 'root'}

Example of a dict comprehensions to create a (pid: info, ...)
data structure:

```python
>>> import psutil
>>> procs = {p.pid: p.info
for p in psutil.process_iter(attrs=['name', 'username'])}
}
>>> procs
{1: {'name': 'systemd', 'username': 'root'},
2: {'name': 'kthreadd', 'username': 'root'},
3: {'name': 'ksoftirqd/0', 'username': 'root'},
...

Example showing how to filter processes by name:

```python
>>> import psutil
>>> [p.info
for p in psutil.process_iter(attrs=['pid', 'name']) if 'python' in p.
...

See also process filtering section for more examples.

Changed in version 5.3.0: added \textit{"attrs"} and \textit{"ad_value"} parameters.

\texttt{psutil.pid_exists(pid)}
Check whether the given PID exists in the current process list. This is faster than doing \texttt{pid in psutil.pids()} and should be preferred.

\texttt{psutil.wait_procs(procs, timeout=None, callback=None)}
Convenience function which waits for a list of Process instances to terminate. Return a \texttt{(gone, alive)}
tuple indicating which processes are gone and which ones are still alive. The \textit{gone} ones will have a new \texttt{return-code}
attribute indicating process exit status (will be \texttt{None} for processes which are not our children). \texttt{callback}
is a function which gets called when one of the processes being waited on is terminated and a Process instance
is passed as callback argument). This function will return as soon as all processes terminate or when \texttt{timeout}
(seconds) occurs. Differently from Process.wait() it will not raise TimeoutExpired if timeout occurs.

A typical use case may be:

\begin{itemize}
  \item send SIGTERM to a list of processes
  \item give them some time to terminate
  \item send SIGKILL to those ones which are still alive
\end{itemize}

Example which terminates and waits all the children of this process:

```python
import psutil

def on_terminate(proc):
    print("process {} terminated with exit code {}.format(proc, proc.returncode))
```
procs = psutil.Process().children()
for p in procs:
    p.terminate()
gone, alive = psutil.wait_procs(procs, timeout=3, callback=on_terminate)
for p in alive:
    p.kill()
methods you can use `is_running()` before querying the process or `process_iter()` in case you’re iterating over all processes. It must be noted though that unless you deal with very “old” (inactive) `Process` instances this will hardly represent a problem.

**oneshot()**

Utility context manager which considerably speeds up the retrieval of multiple process information at the same time. Internally different process info (e.g. `name()`, `ppid()`, `uids()`, `create_time()`, ...) may be fetched by using the same routine, but only one value is returned and the others are discarded. When using this context manager the internal routine is executed once (in the example below on `name()`) the value of interest is returned and the others are cached. The subsequent calls sharing the same internal routine will return the cached value. The cache is cleared when exiting the context manager block. The advice is to use this every time you retrieve more than one information about the process. If you’re lucky, you’ll get a hell of a speedup. Example:

```python
>>> import psutil
>>> p = psutil.Process()
>>> with p.oneshot():
...   p.name()  # execute internal routine once collecting multiple info
...   p.cpu_times()  # return cached value
...   p.cpu_percent()  # return cached value
...   p.create_time()  # return cached value
...   p.ppid()  # return cached value
...   p.status()  # return cached value
...   ...  
>>> 
```

Here’s a list of methods which can take advantage of the speedup depending on what platform you’re on. In the table below horizontal empty rows indicate what process methods can be efficiently grouped together internally. The last column (speedup) shows an approximation of the speedup you can get if you call all the methods together (best case scenario).

New in version 5.0.0.
The process PID. This is the only (read-only) attribute of the class.

The process parent PID. On Windows the return value is cached after first call. Not on POSIX because `ppid` may change if process becomes a zombie. See also `parent()` method.

The process name. On Windows the return value is cached after first call. Not on POSIX because the process name may change. See also how to find a process by name.

The process executable as an absolute path. On some systems this may also be an empty string. The return value is cached after first call.

The command line this process has been called with as a list of strings. The return value is not cached because the cmdline of a process may change.

The environment variables of the process as a dict. Note: this might not reflect changes made after the process started.
psutil Documentation, Release 5.5.0

Availability: Linux, macOS, Windows, SunOS

New in version 4.0.0.

Changed in version 5.3.0: added SunOS support

create_time()
The process creation time as a floating point number expressed in seconds since the epoch, in UTC. The return value is cached after first call.

```python
>>> import psutil, datetime
>>> p = psutil.Process()
>>> p.create_time()
1307289803.47
>>> datetime.datetime.fromtimestamp(p.create_time()).strftime("%Y-%m-%d %H:%M:%S")
'2011-03-05 18:03:52'
```

as_dict (atts=None, ad_value=None)
Utility method retrieving multiple process information as a dictionary. If atts is specified it must be a list of strings reflecting available Process class’s attribute names. Here’s a list of possible string values: 'cmdline', 'connections', 'cpu_affinity', 'cpu_num', 'cpu_percent', 'cpu_times', 'create_time', 'cwd', 'environ', 'exe', 'gids', 'io_counters', 'ionice', 'memory_full_info', 'memory_info', 'memory_maps', 'memory_percent', 'name', 'nice', 'num_ctx_switches', 'num_fds', 'num_handles', 'num_threads', 'open_files', 'pid', 'ppid', 'status', 'terminal', 'threads', 'uids', 'username'. If atts argument is not passed all public read only attributes are assumed. ad_value is the value which gets assigned to a dict key in case AccessDenied or ZombieProcess exception is raised when retrieving that particular process information. Internally, as_dict() uses oneshot() context manager so there’s no need you use it also.

```python
>>> import psutil
>>> p = psutil.Process()
>>> p.as_dict(atts=['pid', 'name', 'username'])
{'username': 'giampaolo', 'pid': 12366, 'name': 'python'}
```

Changed in version 3.0.0: ad_value is used also when incurring into ZombieProcess exception, not only AccessDenied

Changed in version 4.5.0: as_dict() is considerably faster thanks to oneshot() context manager.

parent()
Utility method which returns the parent process as a Process object preemptively checking whether PID has been reused. If no parent PID is known return None. See also ppid() method.

status()
The current process status as a string. The returned string is one of the psutil.STATUS_* constants.

cwd()The process current working directory as an absolute path.

username()
The name of the user that owns the process. On UNIX this is calculated by using real process uid.

uids()The real, effective and saved user ids of this process as a named tuple. This is the same as os.getresuid()
but can be used for any process PID.

Availability: UNIX

gids()

The real, effective and saved group ids of this process as a named tuple. This is the same as os.getresgid() but can be used for any process PID.

Availability: UNIX

terminal()

The terminal associated with this process, if any, else None. This is similar to “tty” command but can be used for any process PID.

Availability: UNIX

nice (value=None)

Get or set process niceness (priority). On UNIX this is a number which usually goes from -20 to 20. The higher the nice value, the lower the priority of the process.

```python
>>> import psutil
>>> p = psutil.Process()
>>> p.nice(10)  # set
10
>>> p.nice()  # get
10
```

Starting from Python 3.3 this functionality is also available as os.getpriority() and os.setpriority() (UNIX only). On Windows this is implemented via GetPriorityClass and SetPriorityClass Windows APIs and value is one of the psutil.*_PRIORITY_CLASS constants reflecting the MSDN documentation. Example which increases process priority on Windows:

```python
>>> p.nice(psutil.HIGH_PRIORITY_CLASS)
```

ionice (ioclass=None, value=None)

Get or set process I/O niceness (priority). On Linux ioclass is one of the psutil.IOPRIO_CLASS_+ constants. value is a number which goes from 0 to 7. The higher the value, the lower the I/O priority of the process. On Windows only ioclass is used and it can be set to 2 (normal), 1 (low) or 0 (very low). The example below sets IDLE priority class for the current process, meaning it will only get I/O time when no other process needs the disk:

```python
>>> import psutil
>>> p = psutil.Process()
>>> p.ionice(psutil.IOPRIO_CLASS_IDLE)  # set
>>> p.ionice()  # get
pionice(ioclass=<IOPriority.IOPRIO_CLASS_IDLE: 3>, value=0)
```

On Windows only ioclass is used and it can be set to 2 (normal), 1 (low) or 0 (very low). Also it returns an integer instead of a named tuple.

Availability: Linux and Windows > Vista

Changed in version 3.0.0: on Python >= 3.4 the returned ioclass constant is an enum instead of a plain integer.

rlimit (resource, limits=None)

Get or set process resource limits (see man prlimit). resource is one of the psutil.RLIMIT_* constants. limits is a (soft, hard) tuple. This is the same as resource.getrlimit() and resource.setrlimit() but can
be used for any process PID, not only os.getpid(). For get, return value is a (soft, hard) tuple. Each value may be either and integer or psutil.RLIMIT_* . Example:

```python
>>> import psutil
>>> p = psutil.Process()
>>> # process may open no more than 128 file descriptors
>>> p.rlimit(psutil.RLIMIT_NOFILE, (128, 128))
>>> # process may create files no bigger than 1024 bytes
>>> p.rlimit(psutil.RLIMIT_FSIZE, (1024, 1024))
>>> # get
>>> p.rlimit(psutil.RLIMIT_FSIZE)
(1024, 1024)
```

Availability: Linux

**io_counters()**

Return process I/O statistics as a named tuple. For Linux you can refer to /proc filesystem documentation.

- **read_count**: the number of read operations performed (cumulative). This is supposed to count the number of read-related syscalls such as read() and pread() on UNIX.
- **write_count**: the number of write operations performed (cumulative). This is supposed to count the number of write-related syscalls such as write() and pwrite() on UNIX.
- **read_bytes**: the number of bytes read (cumulative). Always -1 on BSD.
- **write_bytes**: the number of bytes written (cumulative). Always -1 on BSD.

Linux specific:

- **read_chars** *(Linux)*: the amount of bytes which this process passed to read() and pread() syscalls (cumulative). Differently from read_bytes it doesn’t care whether or not actual physical disk I/O occurred.
- **write_chars** *(Linux)*: the amount of bytes which this process passed to write() and pwrite() syscalls (cumulative). Differently from write_bytes it doesn’t care whether or not actual physical disk I/O occurred.

Windows specific:

- **other_count** *(Windows)*: the number of I/O operations performed other than read and write operations.
- **other_bytes** *(Windows)*: the number of bytes transferred during operations other than read and write operations.

```python
>>> import psutil
>>> p = psutil.Process()
>>> p.io_counters()
pio(read_count=454556, write_count=3456, read_bytes=110592, write_bytes=0, →read_chars=769931, write_chars=203)
```

Availability: Linux, BSD, Windows, AIX

Changed in version 5.2.0: added read_chars and write_chars on Linux; added other_count and other_bytes on Windows.

**num_ctx_switches()**

The number voluntary and involuntary context switches performed by this process (cumulative).

Changed in version 5.4.1: added AIX support
num_fds()
The number of file descriptors currently opened by this process (non cumulative).
Availability: UNIX

num_handles()
The number of handles currently used by this process (non cumulative).
Availability: Windows

num_threads()
The number of threads currently used by this process (non cumulative).

threads()
Return threads opened by process as a list of named tuples including thread id and thread CPU times (user/system). On OpenBSD this method requires root privileges.

cpu_times()
Return a (user, system, children_user, children_system) named tuple representing the accumulated process time, in seconds (see explanation). On Windows and macOS only user and system are filled, the others are set to 0. This is similar to os.times() but can be used for any process PID.

Changed in version 4.1.0: return two extra fields: children_user and children_system.

cpu_percent (interval=None)
Return a float representing the process CPU utilization as a percentage which can also be > 100.0 in case of a process running multiple threads on different CPUs. When interval is > 0.0 compares process times to system CPU times elapsed before and after the interval (blocking). When interval is 0.0 or None compares process times to system CPU times elapsed since last call, returning immediately. That means the first time this is called it will return a meaningless 0.0 value which you are supposed to ignore. In this case is recommended for accuracy that this function be called a second time with at least 0.1 seconds between calls. Example:

```python
>>> import psutil
>>> p = psutil.Process()
>>> # blocking
>>> p.cpu_percent(interval=1)
2.0
>>> # non-blocking (percentage since last call)
>>> p.cpu_percent(interval=None)
2.9
```

Note: the returned value can be > 100.0 in case of a process running multiple threads on different CPU cores.

Note: the returned value is explicitly not split evenly between all available CPUs (differently from psutil.cpu_percent()). This means that a busy loop process running on a system with 2 logical CPUs will be reported as having 100% CPU utilization instead of 50%. This was done in order to be consistent with top UNIX utility and also to make it easier to identify processes hogging CPU resources independently from the number of CPUs. It must be noted that taskmgr.exe on Windows does not behave like this (it would report 50% usage instead). To emulate Windows taskmgr.exe behavior you can do: p.cpu_percent() / psutil.cpu_count().
Warning: the first time this method is called with interval = 0.0 or None it will return a meaningless 0.0 value which you are supposed to ignore.

**cpu_affinity**(cpus=None)
Get or set process current CPU affinity. CPU affinity consists in telling the OS to run a process on a limited set of CPUs only (on Linux cmdline, taskset command is typically used). If no argument is passed it returns the current CPU affinity as a list of integers. If passed it must be a list of integers specifying the new CPUs affinity. If an empty list is passed all eligible CPUs are assumed (and set). On some systems such as Linux this may not necessarily mean all available logical CPUs as in `list(range(psutil.cpu_count()))`.

```python
>>> import psutil
>>> psutil.cpu_count()
4
>>> p = psutil.Process()
>>> # get
>>> p.cpu_affinity()
[0, 1, 2, 3]
>>> # set; from now on, process will run on CPU #0 and #1 only
>>> p.cpu_affinity([0, 1])
>>> p.cpu_affinity()
[0, 1]
>>> # reset affinity against all eligible CPUs
>>> p.cpu_affinity([])
```

Availability: Linux, Windows, FreeBSD

Changed in version 2.2.0: added support for FreeBSD

Changed in version 5.1.0: an empty list can be passed to set affinity against all eligible CPUs.

**cpu_num()**
Return what CPU this process is currently running on. The returned number should be <= `psutil.cpu_count()`. On FreeBSD certain kernel process may return −1. It may be used in conjunction with `psutil.cpu_percent(percpu=True)` to observe the system workload distributed across multiple CPUs as shown by `cpu_distribution.py` example script.

Availability: Linux, FreeBSD, SunOS

New in version 5.1.0.

**memory_info()**
Return a named tuple with variable fields depending on the platform representing memory information about the process. The “portable” fields available on all platforms are `rss` and `vms`. All numbers are expressed in bytes.
• **rss**: aka “Resident Set Size”, this is the non-swapped physical memory a process has used. On UNIX it matches “top”’s RES column (see doc). On Windows this is an alias for wset field and it matches “Mem Usage” column of taskmgr.exe.

• **vms**: aka “Virtual Memory Size”, this is the total amount of virtual memory used by the process. On UNIX it matches “top”’s VIRT column (see doc). On Windows this is an alias for pagefile field and it matches “Mem Usage” “VM Size” column of taskmgr.exe.

• **shared**: (Linux) memory that could be potentially shared with other processes. This matches “top”’s SHR column (see doc).

• **text** (Linux, BSD): aka TRS (text resident set) the amount of memory devoted to executable code. This matches “top”’s CODE column (see doc).

• **data** (Linux, BSD): aka DRS (data resident set) the amount of physical memory devoted to other than executable code. It matches “top”’s DATA column (see doc).

• **lib** (Linux): the memory used by shared libraries.

• **dirty** (Linux): the number of dirty pages.

• **pfaults** (macOS): number of page faults.

• **pageins** (macOS): number of actual pageins.

For on explanation of Windows fields rely on PROCESS_MEMORY_COUNTERS_EX structure doc. Example on Linux:

```python
>>> import psutil
>>> p = psutil.Process()
>>> p.memory_info()
pmem(rss=15491072, vms=84025344, shared=5206016, text=2555904, lib=0, 
→data=9891840, dirty=0)
```

Changed in version 4.0.0: multiple fields are returned, not only `rss` and `vms`.

### memory_info_ex()

Same as `memory_info()` (deprecated).

**Warning:** deprecated in version 4.0.0; use `memory_info()` instead.
**memory_full_info()**

This method returns the same information as `memory_info()`, plus, on some platform (Linux, macOS, Windows), also provides additional metrics (USS, PSS and swap). The additional metrics provide a better representation of “effective” process memory consumption (in case of USS) as explained in detail in this blog post. It does so by passing through the whole process address. As such it usually requires higher user privileges than `memory_info()` and is considerably slower. On platforms where extra fields are not implemented this simply returns the same metrics as `memory_info()`.

- **uss (Linux, macOS, Windows)**: aka “Unique Set Size”, this is the memory which is unique to a process and which would be freed if the process was terminated right now.
- **pss (Linux)**: aka “Proportional Set Size”, is the amount of memory shared with other processes, accounted in a way that the amount is divided evenly between the processes that share it. I.e. if a process has 10 MBs all to itself and 10 MBs shared with another process its PSS will be 15 MBs.
- **swap (Linux)**: amount of memory that has been swapped out to disk.

**Note:** **uss** is probably the most representative metric for determining how much memory is actually being used by a process. It represents the amount of memory that would be freed if the process was terminated right now.

Example on Linux:

```python
>>> import psutil
>>> p = psutil.Process()
>>> p.memory_full_info()

pfullmem(rss=10199040, vms=52133888, shared=3887104, text=2867200, lib=0,
data=5967872, dirty=0, uss=6545408, pss=6872064, swap=0)
```

See also procsmem.py for an example application.

New in version 4.0.0.

**memory_percent** *(memtype="rss")*

Compare process memory to total physical system memory and calculate process memory utilization as a percentage. **memtype** argument is a string that dictates what type of process memory you want to compare against. You can choose between the named tuple field names returned by `memory_info()` and `memory_full_info()` (defaults to "rss").

Changed in version 4.0.0: added **memtype** parameter.

**memory_maps** *(grouped=True)*

Return process’s mapped memory regions as a list of named tuples whose fields are variable depending on the platform. This method is useful to obtain a detailed representation of process memory usage as explained here (the most important value is “private” memory). If **grouped** is **True** the mapped regions with the same **path** are grouped together and the different memory fields are summed. If **grouped** is **False** each mapped region is shown as a single entity and the named tuple will also include the mapped region’s address space (**addr**) and permission set (**perms**). See pmap.py for an example application.
>>> import psutil
>>> p = psutil.Process()
>>> p.memory_maps()
[pmmap_grouped(path='/lib/x8664-linux-gnu/libutil-2.15.so', rss=32768, size=2125824, pss=32768, shared_clean=0, shared_dirty=0, private_clean=20480, private_dirty=12288, referenced=32768, anonymous=12288, swap=0),
 pmmap_grouped(path='/lib/x8664-linux-gnu/libc-2.15.so', rss=3821568, size=3842048, pss=3821568, shared_clean=0, shared_dirty=0, private_clean=0, private_dirty=3821568, referenced=3575808, anonymous=3821568, swap=0),
 pmmap_grouped(path='/lib/x8664-linux-gnu/libcrypto.so.0.1', rss=34124, size=2134016, pss=15360, shared_clean=24576, shared_dirty=0, private_clean=0, private_dirty=8192, referenced=24576, anonymous=8192, swap=0),
 pmmap_grouped(path='[heap]', rss=32768, size=139264, pss=32768, shared_clean=0, shared_dirty=0, private_clean=0, private_dirty=32768, referenced=32768, anonymous=32768, swap=0),
 pmmap_grouped(path='[stack]', rss=2465792, size=2494464, pss=2465792, shared_clean=0, shared_dirty=0, private_clean=0, private_dirty=2465792, referenced=2277376, anonymous=2465792, swap=0),
 ...
]

 Availability: All platforms except OpenBSD, NetBSD and AIX.

children (recursive=False)

5.3. Process class 31
Return the children of this process as a list of `Process` instances. If recursive is `True` return all the parent descendants. Pseudo code example assuming `A` is the current process:

```
A -
   B (child) -
   |
   X (grandchild) -
   |
   C (child)
   |
   D (child)
```

```python
>>> p.children()
B, C, D
>>> p.children(recursive=True)
B, X, Y, C, D
```

Note that in the example above if process X disappears process Y won’t be returned either as the reference to process A is lost. This concept is well summarised by this unit test. See also how to kill a process tree and terminate my children.

### open_files()

Return regular files opened by process as a list of named tuples including the following fields:

- **path**: the absolute file name.
- **fd**: the file descriptor number; on Windows this is always -1.

Linux only:

- **position (Linux)**: the file (offset) position.
- **mode (Linux)**: a string indicating how the file was opened, similarly open’s `mode` argument. Possible values are 'r', 'w', 'a', 'r+' and 'a+'. There’s no distinction between files opened in binary or text mode ("b" or "t").
- **flags (Linux)**: the flags which were passed to the underlying os.open C call when the file was opened (e.g. `os.O_RDONLY`, `os.O_TRUNC`, etc).

```python
>>> import psutil
>>> f = open('file.ext', 'w')
>>> p = psutil.Process()
>>> p.open_files()
[popenfile(path='/home/giampaolo/svn/psutil/file.ext', fd=3, position=0, mode='w', flags=32769)]
```

**Warning:** on Windows this method is not reliable due to some limitations of the underlying Windows API which may hang when retrieving certain file handles. In order to work around that psutil spawns a thread for each handle and kills it if it’s not responding after 100ms. That implies that this method on Windows is not guaranteed to enumerate all regular file handles (see issue 597). Also, it will only list files living in the C:\ drive (see issue 1020).

**Warning:** on BSD this method can return files with a null path (""”) due to a kernel bug, hence it’s not reliable (see issue 595).

Changed in version 3.1.0: no longer hangs on Windows.
connections(kind="inet")

Return socket connections opened by process as a list of named tuples. To get system-wide connections use psutil.net_connections(). Every named tuple provides 6 attributes:

- **fd**: the socket file descriptor. This can be passed to socket.fromfd() to obtain a usable socket object. On Windows, FreeBSD and SunOS this is always set to -1.
- **family**: the address family, either AF_INET, AF_INET6 or AF_UNIX.
- **type**: the address type, either SOCK_STREAM or SOCK_DGRAM.
- **laddr**: the local address as a (ip, port) named tuple or a path in case of AF_UNIX sockets. For UNIX sockets see notes below.
- **raddr**: the remote address as a (ip, port) named tuple or an absolute path in case of UNIX sockets. When the remote endpoint is not connected you'll get an empty tuple (AF_INET*) or "" (AF_UNIX). For UNIX sockets see notes below.
- **status**: represents the status of a TCP connection. The return value is one of the psutil.CONN_* constants. For UDP and UNIX sockets this is always going to be psutil.CONN_NONE.

The kind parameter is a string which filters for connections that fit the following criteria:

<table>
<thead>
<tr>
<th>Kind value</th>
<th>Connections using</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;inet&quot;</td>
<td>IPv4 and IPv6</td>
</tr>
<tr>
<td>&quot;inet4&quot;</td>
<td>IPv4</td>
</tr>
<tr>
<td>&quot;inet6&quot;</td>
<td>IPv6</td>
</tr>
<tr>
<td>&quot;tcp&quot;</td>
<td>TCP</td>
</tr>
<tr>
<td>&quot;tcp4&quot;</td>
<td>TCP over IPv4</td>
</tr>
<tr>
<td>&quot;tcp6&quot;</td>
<td>TCP over IPv6</td>
</tr>
<tr>
<td>&quot;udp&quot;</td>
<td>UDP</td>
</tr>
<tr>
<td>&quot;udp4&quot;</td>
<td>UDP over IPv4</td>
</tr>
<tr>
<td>&quot;udp6&quot;</td>
<td>UDP over IPv6</td>
</tr>
<tr>
<td>&quot;unix&quot;</td>
<td>UNIX socket (both UDP and TCP protocols)</td>
</tr>
<tr>
<td>&quot;all&quot;</td>
<td>the sum of all the possible families and protocols</td>
</tr>
</tbody>
</table>

Example:

```python
>>> import psutil
>>> p = psutil.Process(1694)
>>> p.name()
'firefox'
>>> p.connections()
[pconn(fd=115, family=<AddressFamily.AF_INET: 2>, type=<SocketType.SOCK_STREAM: 1>, laddr=addr(ip='10.0.0.1', port=48776), raddr=addr(ip='93.186.135.91', port=80), status='ESTABLISHED'),
 pconn(fd=117, family=<AddressFamily.AF_INET: 2>, type=<SocketType.SOCK_STREAM: 1>, laddr=addr(ip='10.0.0.1', port=43761), raddr=addr(ip='72.14.234.100', port=80), status='CLOSING'),
 pconn(fd=119, family=<AddressFamily.AF_INET: 2>, type=<SocketType.SOCK_STREAM: 1>, laddr=addr(ip='10.0.0.1', port=60759), raddr=addr(ip='72.14.234.104', port=80), status='ESTABLISHED'),
 pconn(fd=123, family=<AddressFamily.AF_INET: 2>, type=<SocketType.SOCK_STREAM: 1>, laddr=addr(ip='10.0.0.1', port=51314), raddr=addr(ip='72.14.234.83', port=443), status='SYN_SENT')]
```
Note: (Solaris) UNIX sockets are not supported.

Note: (Linux, FreeBSD) “raddr” field for UNIX sockets is always set to “”. This is a limitation of the OS.

Note: (OpenBSD) “laddr” and “raddr” fields for UNIX sockets are always set to “”. This is a limitation of the OS.

Note: (AIX) psutil.AccessDenied is always raised unless running as root (lsof does the same).

Changed in version 5.3.0: “laddr” and “raddr” are named tuples.

**is_running()**
Return whether the current process is running in the current process list. This is reliable also in case the process is gone and its PID reused by another process, therefore it must be preferred over doing psutil.pid_exists(p.pid).

Note: this will return True also if the process is a zombie (p.status() == psutil.STATUS_ZOMBIE).

**send_signal(signal)**
Send a signal to process (see signal module constants) preemptively checking whether PID has been reused. On UNIX this is the same as os.kill(pid, sig). On Windows only SIGTERM, CTRL_C_EVENT and CTRL_BREAK_EVENT signals are supported and SIGTERM is treated as an alias for kill(). See also how to kill a process tree and terminate my children.

Changed in version 3.2.0: support for CTRL_C_EVENT and CTRL_BREAK_EVENT signals on Windows was added.

**suspend()**
Suspend process execution with SIGSTOP signal preemptively checking whether PID has been reused. On UNIX this is the same as os.kill(pid, signal.SIGSTOP). On Windows this is done by suspending all process threads execution.

**resume()**
Resume process execution with SIGCONT signal preemptively checking whether PID has been reused. On UNIX this is the same as os.kill(pid, signal.SIGCONT). On Windows this is done by resuming all process threads execution.

**terminate()**
Terminate the process with SIGTERM signal preemptively checking whether PID has been reused. On UNIX this is the same as os.kill(pid, signal.SIGTERM). On Windows this is an alias for kill(). See also how to kill a process tree and terminate my children.

**kill()**
Kill the current process by using SIGKILL signal preemptively checking whether PID has been reused. On UNIX this is the same as os.kill(pid, signal.SIGKILL). On Windows this is done by using TerminateProcess. See also how to kill a process tree and terminate my children.

**wait(timeout=None)**
Wait for process termination and if the process is a child of the current one also return the exit code,
else None. On Windows there’s no such limitation (exit code is always returned). If the process is already terminated immediately return None instead of raising NoSuchProcess. timeout is expressed in seconds. If specified and the process is still alive raise TimeoutExpired exception. timeout=0 can be used in non-blocking apps: it will either return immediately or raise TimeoutExpired. To wait for multiple processes use psutil.wait_procs().

```python
>>> import psutil
>>> p = psutil.Process(9891)
>>> p.terminate()
>>> p.wait()
```

## 5.4 Popen class

```python
>>> import psutil
>>> from subprocess import PIPE

>>> p = psutil.Popen(["/usr/bin/python", "-c", "print('hello')"], stdout=PIPE)
>>> p.name()
'python'
>>> p.username()
'giampaolo'
>>> p.communicate()
('hello\n', None)
>>> p.wait(timeout=2)
0
```

**psutil.Popen** objects are supported as context managers via the with statement: on exit, standard file descriptors are closed, and the process is waited for. This is supported on all Python versions.

```python
>>> import psutil, subprocess
>>> with psutil.Popen(["ifconfig"], stdout=subprocess.PIPE) as proc:
...    log.write(proc.stdout.read())
```

Changed in version 4.4.0: added context manager support
psutil\_.win_service_iter\_(\)
   Return an iterator yielding a WindowsService class instance for all Windows services installed.
   New in version 4.2.0.
   Availability: Windows

psutil\_.win_service_get\_(name)
   Get a Windows service by name, returning a WindowsService instance. Raise psutil.NoSuchProcess
   if no service with such name exists.
   New in version 4.2.0.
   Availability: Windows

class psutil.WindowsService
   Represents a Windows service with the given name. This class is returned by win_service_iter() and
   win_service_get() functions and it is not supposed to be instantiated directly.

   name()
      The service name. This string is how a service is referenced and can be passed to win_service_get()
      to get a new WindowsService instance.

   display_name()
      The service display name. The value is cached when this class is instantiated.

   binpath()
      The fully qualified path to the service binary/exe file as a string, including command line arguments.

   username()
      The name of the user that owns this service.

   start_type()
      A string which can either be “automatic”, “manual” or “disabled”.

   pid()
      The process PID, if any, else None. This can be passed to Process class to control the service’s process.
status()
Service status as a string, which may be either “running”, “paused”, “start_pending”, “pause_pending”, “continue_pending”, “stop_pending” or “stopped”.

description()
Service long description.

as_dict()
Utility method retrieving all the information above as a dictionary.

New in version 4.2.0.
Availability: Windows

Example code:

```python
>>> import psutil

>>> list(psutil.win_service_iter())
[<WindowsService(name='AeLookupSvc', display_name='Application Experience') at 38850096>,
 <WindowsService(name='ALG', display_name='Application Layer Gateway Service') at 38850128>,
 <WindowsService(name='APNMCP', display_name='Ask Update Service') at 38850160>,
 <WindowsService(name='AppIDSvc', display_name='Application Identity') at 38850192>,
 ...
]

>>> s = psutil.win_service_get('alg')

>>> s.as_dict()
{'binpath': 'C:\Windows\System32\alg.exe',
 'description': 'Provides support for 3rd party protocol plug-ins for Internet_
 Connection Sharing',
 'display_name': 'Application Layer Gateway Service',
 'name': 'alg',
 'pid': None,
 'start_type': 'manual',
 'status': 'stopped',
 'username': 'NT AUTHORITY\LocalService'}
```
psutil.POSIX
psutil.WINDOWS
psutil.LINUX
psutil.MACOS
psutil.FREEBSD
psutil.NETBSD
psutil.OPENBSD
psutil.BSD
psutil.SUNOS
psutil.AIX

   bool constants which define what platform you’re on. E.g. if on Windows, WINDOWS constant will be True, all others will be False.

   New in version 4.0.0.

   Changed in version 5.4.0: added AIX

psutil.OSX

   Alias for MACOS (deprecated).

[Warning] deprecated in version 5.4.7; use MACOS instead.

psutil.PROCFS_PATH

   The path of the /proc filesystem on Linux, Solaris and AIX (defaults to "/proc"). You may want to re-set this constant right after importing psutil in case your /proc filesystem is mounted elsewhere or if you want to retrieve information about Linux containers such as Docker, Heroku or LXC (see here for more info). It must be noted that this trick works only for APIs which rely on /proc filesystem (e.g. memory APIs and most Process class methods).
Availability: Linux, Solaris, AIX

New in version 3.2.3.

Changed in version 3.4.2: also available on Solaris.

Changed in version 5.4.0: also available on AIX.

psutil.STATUS_RUNNING
psutil.STATUS_SLEEPING
psutil.STATUS_DISK_SLEEP
psutil.STATUS_STOPPED
psutil.STATUS_TRACING_STOP
psutil.STATUS_ZOMBIE
psutil.STATUS_DEAD
psutil.STATUS_WAKE_KILL
psutil.STATUS_WAKING
psutil.STATUS_PARKED (Linux)
psutil.STATUS_IDLE (Linux, macOS, FreeBSD)
psutil.STATUS_LOCKED (FreeBSD)
psutil.STATUS_WAITING (FreeBSD)
psutil.STATUS_SUSPENDED (NetBSD)

A set of strings representing the status of a process. Returned by psutil.Process.status().

New in version 3.4.1: STATUS_SUSPENDED (NetBSD)

New in version 5.4.7: STATUS_PARKED (Linux)

psutil.CONN_ESTABLISHED
psutil.CONN_SYN_SENT
psutil.CONN_SYN_RECV
psutil.CONN_FIN_WAIT1
psutil.CONN_FIN_WAIT2
psutil.CONN_TIME_WAIT
psutil.CONN_CLOSE
psutil.CONN_CLOSE_WAIT
psutil.CONN_LAST_ACK
psutil.CONN_LISTEN
psutil.CONN_CLOSING
psutil.CONN_NONE
psutil.CONN_DELETE_TCB (Windows)
psutil.CONN_IDLE (Solaris)
psutil.CONN_BOUND (Solaris)
connections() (status field).

psutil.ABOVE_NORMAL_PRIORITY_CLASS
psutil.BELOW_NORMAL_PRIORITY_CLASS
psutil.HIGH_PRIORITY_CLASS
psutil.IDLE_PRIORITY_CLASS
psutil.NORMAL_PRIORITY_CLASS
psutil.REALTIME_PRIORITY_CLASS
A set of integers representing the priority of a process on Windows (see MSDN documentation). They can be
used in conjunction with psutil.Process.nice() to get or set process priority.

Availability: Windows

Changed in version 3.0.0: on Python >= 3.4 these constants are enums instead of a plain integer.

psutil.IOPRIO_CLASS_NONE
psutil.IOPRIO_CLASS_RT
psutil.IOPRIO_CLASS_BE
psutil.IOPRIO_CLASS_IDLE
A set of integers representing the I/O priority of a process on Linux. They can be used in conjunction
with psutil.Process.ionice() to get or set process I/O priority. IOPRIO_CLASS_NONE and IOPRIO_CLASS_BE (best effort) is the default for any process that hasn’t set a specific I/O priority. IOPRIO_CLASS_RT (real time) means the process is given first access to the disk, regardless of what else is going on in the system. IOPRIO_CLASS_IDLE means the process will get I/O time when no-one else needs the disk. For further information refer to manuals of ionice command line utility or ioprio_get system call.

Availability: Linux

Changed in version 3.0.0: on Python >= 3.4 these constants are enums instead of a plain integer.

psutil.RLIM_INFINITY
psutil.RLIMIT_AS
psutil.RLIMIT_CORE
psutil.RLIMIT_CPU
psutil.RLIMIT_DATA
psutil.RLIMIT_FSIZE
psutil.RLIMIT_LOCKS
psutil.RLIMIT_MEMLOCK
psutil.RLIMIT_MSGQUEUE
psutil.RLIMIT_NICE
psutil.RLIMIT_NOFILE
psutil.RLIMIT_NPROC
psutil.RLIMIT_RSS
psutil.RLIMIT_RTPRIO
Constants used for getting and setting process resource limits to be used in conjunction with `psutil.Process.rlimit()`. See man `prlimit` for further information.

Availability: Linux

```
AF_LINK
```

Constant which identifies a MAC address associated with a network interface. To be used in conjunction with `psutil.net_if_addrs()`.

New in version 3.0.0.

```
NIC_DUPLEX_FULL
NIC_DUPLEX_HALF
NIC_DUPLEX_UNKNOWN
```

Constants which identify whether a NIC (network interface card) has full or half mode speed. `NIC_DUPLEX_FULL` means the NIC is able to send and receive data (files) simultaneously, `NIC_DUPLEX_HALF` means the NIC can either send or receive data at a time. To be used in conjunction with `psutil.net_if_stats()`.

New in version 3.0.0.

```
POWER_TIME_UNKNOWN
POWER_TIME_UNLIMITED
```

Whether the remaining time of the battery cannot be determined or is unlimited. May be assigned to `psutil.sensors_battery()`’s `secsleft` field.

New in version 5.1.0.

```
version_info
```

A tuple to check psutil installed version. Example:

```python
>>> import psutil
>>> if psutil.version_info >= (4, 5):
...    pass
```
Starting from version 5.3.0 psutil fully supports unicode, see issue #1040. The notes below apply to any API returning a string such as\texttt{Process.exe()} or \texttt{Process.cwd()}, including non-filesystem related methods such as\texttt{Process.username()} or \texttt{WindowsService.description()}:

- all strings are encoded by using the OS filesystem encoding (\texttt{sys.getfilesystemencoding()}) which varies depending on the platform (e.g. “UTF-8” on macOS, “mbcs” on Win)
- no API call is supposed to crash with \texttt{UnicodeDecodeError}
- instead, in case of badly encoded data returned by the OS, the following error handlers are used to replace the corrupted characters:
  - Python 3: \texttt{sys.getfilesystemencodeerrors()} (PY 3.6+) or “surrogatescape” on POSIX and “replace” on Windows
  - Python 2: “replace”
- on Python 2 all APIs return bytes (\texttt{str} type), never unicode
- on Python 2, you can go back to unicode by doing:
  ```
  >>> unicode(p.exe(), sys.getdefaultencoding(), errors="replace")
  ```

Example which filters processes with a funky name working with both Python 2 and 3:

```python
# -*- coding: utf-8 -*-
import psutil, sys

PY3 = sys.version_info[0] == 2
LOOKFOR = u"fŏó"
for proc in psutil.process_iter(attrs=['name']):
    name = proc.info['name']
    if not PY3:
        name = unicode(name, sys.getdefaultencoding(), errors="replace")
    if LOOKFOR == name:
        print("process $s found" % p)
```
Follows a collection of utilities and examples which are common but not generic enough to be part of the public API.

### 9.1 Find process by name

Check string against `Process.name()`:

```python
import psutil

def find_procs_by_name(name):
    """Return a list of processes matching 'name'.""
    ls = []
    for p in psutil.process_iter(attrs=['name']):
        if p.info['name'] == name:
            ls.append(p)
    return ls
```

A bit more advanced, check string against `Process.name()`, `Process.exe()` and `Process.cmdline()`:

```python
import os
import psutil

def find_procs_by_name(name):
    """Return a list of processes matching 'name'.""
    ls = []
    for p in psutil.process_iter(attrs=['name', 'exe', 'cmdline']):
        if name == p.info['name'] or \
        p.info['exe'] and os.path.basename(p.info['exe']) == name or \
        p.info['cmdline'] and p.info['cmdline'][0] == name:
            ls.append(p)
    return ls
```
9.2 Kill process tree

```python
import os
import signal
import psutil

def kill_proc_tree(pid, sig=signal.SIGTERM, include_parent=True,
                    timeout=None, on_terminate=None):
    """Kill a process tree (including grandchildren) with signal "sig" and return a (gone, still_alive) tuple. "on_terminate", if specified, is a callabck function which is called as soon as a child terminates. ""
    if pid == os.getpid():
        raise RuntimeError("I refuse to kill myself")
    parent = psutil.Process(pid)
    children = parent.children(recursive=True)
    if include_parent:
        children.append(parent)
    for p in children:
        p.send_signal(sig)
    gone, alive = psutil.wait_procs(children, timeout=timeout,
                                    callback=on_terminate)
    return (gone, alive)
```

9.3 Terminate my children

This may be useful in unit tests whenever sub-processes are started. This will help ensure that no extra children (zombies) stick around to hog resources.

```python
import psutil

def reap_children(timeout=3):
    """Tries hard to terminate and ultimately kill all the children of this process."
    def on_terminate(proc):
        print("process {} terminated with exit code {}".format(proc, proc.returncode))

    procs = psutil.Process().children()
    # send SIGTERM
    for p in procs:
        p.terminate()
    gone, alive = psutil.wait_procs(procs, timeout=timeout, callback=on_terminate)
    if alive:
        # send SIGKILL
        for p in alive:
            print("process {} survived SIGTERM; trying SIGKILL" % p)
            p.kill()
        gone, alive = psutil.wait_procs(alive, timeout=timeout, callback=on_terminate)
    if alive:
        # give up
        for p in alive:
            print("process {} survived SIGKILL; giving up" % p)
```

9.4 Filtering and sorting processes

This is a collection of one-liners showing how to use `process_iter()` in order to filter for processes and sort them.

Setup:

```python
>>> import psutil
>>> from pprint import pprint as pp
```

Processes having “python” in their name:

```python
>>> pp([p.info for p in psutil.process_iter(attrs=['pid', 'name']) if 'python' in p.info['name']])
[{'name': 'python3', 'pid': 21947},
 {'name': 'python', 'pid': 23835}]
```

Processes owned by user:

```python
>>> import getpass
>>> pp([(p.pid, p.info['name']) for p in psutil.process_iter(attrs=['name', 'username']) if p.info['username'] == getpass.getuser()])
[(16832, 'bash'),
 (19772, 'ssh'),
 (20492, 'python')]
```

Processes actively running:

```python
>>> pp([(p.pid, p.info['name'], p.info['status']) for p in psutil.process_iter(attrs=['name', 'status']) if p.info['status'] == psutil.STATUS_RUNNING])
[(1150, {'name': 'Xorg', 'status': 'running'}),
 (1776, {'name': 'unity-panel-service', 'status': 'running'}),
 (20492, {'name': 'python', 'status': 'running'})]
```

Processes using log files:

```python
>>> import os
>>> import psutil
>>> for p in psutil.process_iter(attrs=['name', 'open_files']):
...     for file in p.info['open_files'] or []:
...         if os.path.splitext(file.path)[1] == '.log':
...             print("%-5s %-10s %s
" % (p.pid, p.info['name'][:10], file.path))
...
1510 upstart /home/giampaolo/.cache/upstart/unity-settings-daemon.log
2174 nautilus /home/giampaolo/.local/share/gvfs-metadata/home-ce08efac.log
2650 chrome /home/giampaolo/.config/google-chrome/Default/data_reduction_proxy_leveldb/000003.log
```

Processes consuming more than 500M of memory:

```python
>>> pp([(p.pid, p.info['name'], p.info['memory_info'].rss) for p in psutil.process_iter(attrs=['name', 'memory_info']) if p.info['memory_info'].rss > 500 * 1024 * 1024])
[(2650, 'chrome', 532324352),
 (3038, 'chrome', 1120088064),
 (21915, 'sublime_text', 615407616)]
```

Top 3 most memory consuming processes:
Top 3 processes which consumed the most CPU time:

```python
>>> pp([(p.pid, p.info['name'], sum(p.info['cpu_times'])) for p in sorted(psutil.process_iter(attrs=['name', 'cpu_times']), key=lambda p: sum(p.info['cpu_times'][:2]))][-3:]
[(2721, 'chrome', 10219.73),
 (1150, 'Xorg', 11116.98999999998),
 (2650, 'chrome', 18451.97)]
```

Top 3 processes which caused the most I/O:

```python
>>> pp([(p.pid, p.info['name']) for p in sorted(psutil.process_iter(attrs=['name', 'io_counters']), key=lambda p: p.info['io_counters'][:2])][-3:]
[(21915, 'sublime_text'),
 (1871, 'pulseaudio'),
 (1510, 'upstart')]
```

Top 3 processes opening more file descriptors:

```python
>>> pp([(p.pid, p.info) for p in sorted(psutil.process_iter(attrs=['name', 'num_fds']), key=lambda p: p.info['num_fds'])][-3:]
[(21915, {'name': 'sublime_text', 'num_fds': 105}),
 (2721, {'name': 'chrome', 'num_fds': 185}),
 (2650, {'name': 'chrome', 'num_fds': 354})]
```

### 9.5 Bytes conversion

```python
import psutil
def bytes2human(n):
    # http://code.activestate.com/recipes/578019
    # >>> bytes2human(10000)
    # '9.8K'
    # >>> bytes2human(100001221)
    # '95.4M'
    symbols = ('K', 'M', 'G', 'T', 'P', 'E', 'Z', 'Y')
    prefix = {}
    for i, s in enumerate(symbols):
        prefix[s] = 1 << (i + 1) * 10
    for s in reversed(symbols):
        if n >= prefix[s]:
            value = float(n) / prefix[s]
            return '%.1f%s % (value, s)
    return '%sB' % n

total = psutil.disk_usage('/').total
print(total)
print(bytes2human(total))
```
...prints:

FAQs

• Q: What Windows versions are supported?
  • A: From Windows Vista onwards, both 32 and 64 bit versions. Latest binary (wheel / exe) release which supports Windows 2000, XP and 2003 server is psutil 3.4.2. On such old systems psutil is no longer tested or maintained, but it can still be compiled from sources (you’ll need Visual Studio) and it should “work” (more or less).

• Q: What Python versions are supported?
  • A: From 2.6 to 3.6, both 32 and 64 bit versions. Last version supporting Python 2.4 and 2.5 is psutil 2.1.3. PyPy is also known to work.

• Q: What SunOS versions are supported?
  • A: From Solaris 10 onwards.

• Q: Why do I get AccessDenied for certain processes?
  • A: This may happen when you query processes owned by another user, especially on macOS and Windows. Unfortunately there’s not much you can do about this except running the Python process with higher privileges. On Unix you may run the the Python process as root or use the SUID bit (this is the trick used by tools such as ps and netstat). On Windows you may run the Python process as NT AUTHORITY\SYSTEM or install the Python script as a Windows service (this is the trick used by tools such as ProcessHacker).

• Q: What about load average?
  • A: psutil does not expose any load average function as it’s already available in python as os.getloadavg.
Running tests

There are two ways of running tests. If psutil is already installed use:

$ python -m psutil.tests

You can use this method as a quick way to make sure psutil fully works on your platform. If you have a copy of the source code you can also use:

$ make test
Development guide

If you plan on hacking on psutil (e.g. want to add a new feature or fix a bug) take a look at the development guide.
