Introduction

The `pyaardvark` module tries to provide a very simple API to use the [Total Phase Aardvark I²C/SPI Host adapter](#) within your python program.

Simple Example

In this example we access an I²C-EEPROM on address `0x50` and read the first five bytes of its content:

```
import pyaardvark

a = pyaardvark.open()
data = a.i2c_master_write_read(0x50, '\x00', 5)
# data = '\x00\x01\x02\x03\x04'
a.close()
```

Easy, huh?

For those, who are not familiar with I²C-EEPROM accesses: You first write the offset to read from to the device (`0x00` in the example above) and then you read the desired amount of bytes from the device. The offset counter will automatically be incremented. Therefore, in the example above you read the bytes at the offsets 0, 1, 2, 3 and 4. Please note, that there are byte- and word-addressable EEPROMs. In this example we assumed a byte-addressable one, because our offset is only one byte.

Tutorial

Opening an Aardvark device

You have three choices to open your Aardvark device. The first is the one you saw in the simple example above:

```
a = pyaardvark.open()
```

If you have only one device connected to your machine, this is all you have to do. `pyaardvark.open()` automatically uses the first device it finds.

If you have multiple devices connected, you can either use the port parameter:

```
a = pyaardvark.open(1)
```

or the serial number, which you can find on the device itself or in your USB properties of your machine:

```
a = pyaardvark.open(serial_number='1111-222222')
```

In all cases `pyaardvark.open()` returns an `pyaardvark.Aardvark` object, which then can be used to access the host adapter.

Using the context manager protocol to open an Aardvark device

All methods of the `pyaardvark.Aardvark` object can raise an `IOError`. Instead of using `try .. except .. finally ..` you can use the `with` statement to open the device. Closing the device will then happen automatically after the block:

```
with pyaardvark.open() as a:
    print a.api_version
# no need for a.close() here
```

Accessing your I²C and SPI devices

To issue I²C or SPI transactions you have to first configure the adapter in the corresponding output mode. Each interface, I²C or SPI, can either be GPIOs or the actual interface. So if, for example you want to use both I²C and SPI at the same time and none of them as GPIOs:

```
a.enable_i2c = True
a.enable_spi = True
```

After you enabled the I²C interface you can issue transactions on the bus:

```
a.i2c_master_write(0x50, '\x00\x02\x00\x00')
```

This will write address device `0x50` and sends the byte sequence `0x00, 0x02, 0x00, 0x00` to it. To read from a device use `pyaardvark.Aardvark.i2c_master_read()`. Eventually, both can be combined and issued in one transaction: `pyaardvark.Aardvark.i2c_master_write_read()`.

Closing the device

Releasing the device can be done with `pyaardvark.Aardvark.close()`:

```
a.close()
```

FAQ

Convert data to a string

Most parameters of the pyaardvark API take (byte) strings (eg. `pyaardvark.Aardvark.i2c_master_write_read()` etc). You can convert iterables to strings using the built-in `chr` function:

```
data = (0x01, 0xaf, 0xff)
data = ''.join(chr(c) for c in data) # data is '\x01\xaf\xff'
a.i2c_master_write(0x50, data)      # writes 1h, AFh, FFh to address 50h
```

To convert a character/string to a number you can use the built-in `ord` function:

```
data_str = a.i2c_master_read(0x50, 3) # data_str is '\xc0\x01\xff'
data = [ord(b) for b in data_str]     # data is [192, 1, 255]
```

Module Interface

`pyaardvark.find_devices()`

Return a list of dictionaries. Each dictionary represents one device.

The dictionary contains the following keys: `port`, `unique_id` and `in_use`. `port` can be used with `open()`. `serial_number` is the serial number of the device (and can also be used with `open()`) and `in_use` indicates whether the device was opened before and can currently not be opened.

Note: There is no guarantee, that the returned information is still valid when you open the device. Esp. if you open a device by the port, the `unique_id` may change because you've just opened another device. Eg. it may be disconnected from the machine after you call `find_devices()` but before you call `open()`.

To open a device by its serial number, you should use the `open()` with the `serial_number` parameter.

`pyaardvark.open(port=None, serial_number=None)`

Open an aardvark device and return an `Aardvark` object. If the device cannot be opened an `IOError` is raised.

The `port` can be retrieved by `find_devices()`. Usually, the first device is 0, the second 1, etc.

If you are using only one device, you can therefore omit the parameter in which case 0 is used.

Another method to open a device is to use the serial number. You can either find the number on the device itself or in the in the corresponding USB property. The serial number is a string which looks like `NNNN-MMMMMMM`.

Raises an `IOError` if the port (or serial number) does not exist, is already connected or an incompatible device is found.

Note: There is a small chance that this function raises an `IOError` although the correct device is available and not opened. The open-by-serial-number method works by scanning the devices. But as explained in `find_devices()`, the returned information may be outdated. Therefore, `open()` checks the serial number once the device is opened and if it is not the expected one, raises `IOError`. No retry mechanism is implemented.

As long as nobody comes along with a better idea, this failure case is up to the user.

Aardvark Object

class `pyaardvark.Aardvark` (*port=0*)

Represents an Aardvark device.

api_version = `None`

Version of underlying C module (aardvark.so, aardvark.dll) as a string. See *hardware_revision* for more information on the format.

close ()

Close the device.

disable_i2c_monitor ()

Disable the I2C monitor.

Raises an `IOError` if the hardware adapter does not support monitor mode.

disable_i2c_slave ()

Disable I2C slave mode.

enable_i2c

Set this to `True` to enable the hardware I2C interface. If set to `False` the hardware interface will be disabled and its pins (SDA and SCL) can be used as GPIOs.

enable_i2c_monitor ()

Activate the I2C monitor.

Enabling the monitor will disable all other functions of the adapter.

Raises an `IOError` if the hardware adapter does not support monitor mode.

enable_i2c_slave (*slave_address*)

Enable I2C slave mode.

The device will respond to the specified *slave_address* if it is addressed.

You can wait for the data with `poll ()` and get it with `i2c_slave_read`.

enable_spi

Set this to `True` to enable the hardware SPI interface. If set to `False` the hardware interface will be disabled and its pins (MISO, MOSI, SCK and SS) can be used as GPIOs.

firmware_version = `None`

Firmware version of the host adapter as a string. See *hardware_revision* for more information on the format.

handle = `None`

A handle which is used as the first paramter for all calls to the underlying API.

hardware_revision = `None`

Hardware revision of the host adapter as a string. The format is *M.NN* where *M* is the major number and *NN* the zero padded minor number.

i2c_bitrate

I2C bitrate in kHz. Not every bitrate is supported by the host adapter. Therefore, the actual bitrate may be less than the value which is set.

The power-on default value is 100 kHz.

i2c_master_read (*addr, length, flags=0*)

Make an I2C read access.

The given I2C device is addressed and clock cycles for *length* bytes are generated. A short read will occur if the device generates an early NAK.

The transaction is finished with an I2C stop condition unless the I2C_NO_STOP flag is set.

i2c_master_write (*i2c_address, data, flags=0*)

Make an I2C write access.

The given I2C device is addressed and data given as a string is written. The transaction is finished with an I2C stop condition unless I2C_NO_STOP is set in the flags.

10 bit addresses are supported if the I2C_10_BIT_ADDR flag is set.

i2c_master_write_read (*i2c_address, data, length*)

Make an I2C write/read access.

First an I2C write access is issued. No stop condition will be generated. Instead the read access begins with a repeated start.

This method is useful for accessing most addressable I2C devices like EEPROMs, port expander, etc.

Basically, this is just a convenient function which internally uses *i2c_master_write* and *i2c_master_read*.

i2c_monitor_read ()

Retrieved any data fetched by the monitor.

This function has an integrated timeout mechanism. You should use *poll* () to determine if there is any data available.

Returns a list of data bytes and special symbols. There are three special symbols: *I2C_MONITOR_NACK*, *I2C_MONITOR_START* and *I2C_MONITOR_STOP*.

i2c_pullups

Setting this to *True* will enable the I2C pullup resistors. If set to *False* the pullup resistors will be disabled.

Raises an `IOError` if the hardware adapter does not support pullup resistors.

i2c_slave_read ()

Read the bytes from an I2C slave reception.

The bytes are returns as an string object.

poll (*timeout=None*)

Wait for an event to occur.

If *timeout* is given, it specifies the length of time in milliseconds which the function will wait for events before returning. If *timeout* is omitted, negative or *None*, the call will block until there is an event.

Returns a list of events. In case no event is pending, an empty list is returned.

spi_bitrate

SPI bitrate in kHz. Not every bitrate is supported by the host adapter. Therefore, the actual bitrate may be less than the value which is set. The slowest bitrate supported is 125kHz. Any smaller value will be rounded up to 125kHz.

The power-on default value is 1000 kHz.

spi_configure (*polarity, phase, bitorder*)

Configure the SPI interface.

spi_configure_mode (*spi_mode*)

Configure the SPI interface by the well known SPI modes.

spi_ss_polarity (*polarity*)

Change the output polarity on the SS line.

Please note, that this only affects the master functions.

spi_write (*data*)

Write a stream of bytes to a SPI device.

target_power

Setting this to *True* will activate the power pins (4 and 6). If set to *False* the power will be deactivated.

Raises an `IOError` if the hardware adapter does not support the switchable power pins.

unique_id ()

Return the unique identifier of the device. The identifier is the serial number you can find on the adapter without the dash. Eg. the serial number 0012-345678 would be 12345678.

unique_id_str ()

Return the unique identifier. But unlike `unique_id()`, the ID is returned as a string which has the format NNNN-MMMMMMM.
