13	Indices and tables	57
14	Resources	59
	Python Module Index	61

scikit-build is an improved build system generator for CPython C extensions. It provides better support for additional compilers, build systems, cross compilation, and locating dependencies and their associated build requirements.

The **scikit-build** package is fundamentally just glue between the *setuptools* Python module and [CMake](#). Currently, the package is available to perform builds in a *setup.py* file. In the future, the project aims to be a build tool option in the [currently developing pyproject.toml](#) build system specification.

1.1 Install package with pip

To install with pip:

```
$ pip install scikit-build
```

1.2 Install from source

To install scikit-build from the latest source, first obtain the source code:

```
$ git clone https://github.com/scikit-build/scikit-build
$ cd scikit-build
```

then install with:

```
$ pip install .
```

or:

```
$ pip install -e .
```

for development.

1.3 Dependencies

1.3.1 Python Packages

The project has a few common Python package dependencies. The runtime dependencies are:

```
wheel>=0.29.0
setuptools>=28.0.0
```

The build time dependencies (also required for development) are:

```
codecov>=2.0.5
coverage>=4.2
cython>=0.25.1
flake8>=3.0.4
path.py>=8.2.1
pytest>=3.0.3
pytest-cov>=2.4.0
pytest-mock>=1.4.0
pytest-runner>=2.9
pytest-virtualenv>=1.2.5
six>=1.10.0
```

1.3.2 Compiler Toolchain

The same compiler toolchain used to build the CPython interpreter should also be available. Refer to the [CPython Developer's Guide](#) for details about the compiler toolchain for your operating system.

For example, on *Ubuntu Linux*, install with:

```
$ sudo apt-get install build-essential
```

On *Mac OSX*, install [XCode](#) to build packages for the system Python.

On Windows, install the version of [Visual Studio](#) used to create the target version of CPython

1.3.3 CMake

Download standard [CMake binaries](#) for your platform. Alternatively, build CMake from source with a C++ compiler if binaries are not available for your operating system.

Why should I use scikit-build ?

Scikit-build is a replacement for `distutils.core.Extension` with the following advantages:

- provide better support for *additional compilers and build systems*
- first-class *cross-compilation* support
- location of dependencies and their associated build requirements

3.1 Basic usage

To use scikit-build in a project, place the following in your project's `setup.py` file:

```
# This line replaces 'from setuptools import setup'  
from skbuild import setup
```

Your project now uses scikit-build instead of setuptools.

Next, add a `CMakeLists.txt`

Note: *To be documented.*

3.2 Setup options

Scikit-build augments the `setup()` function with the following options:

- `cmake_args`: List of CMake options.

For example:

```
setup(  
    [...]  
    cmake_args=['-DSOME_FEATURE:BOOL=OFF']  
    [...]  
)
```

- `cmake_install_dir`: relative directory where the CMake artifacts are installed. By default, it is set to an empty string.

- `cmake_source_dir`: Relative directory containing the project `CMakeLists.txt`. By default, it is set to the top-level directory where `setup.py` is found.

New in version 0.5.0.

- `cmake_with_sdist`: Boolean indicating if CMake should be executed when running `sdist` command. Setting this option to `True` is useful when part of the sources specified in `MANIFEST.in` are downloaded by CMake. By default, this option is `False`.

3.3 Command line options

```
usage: setup.py [global_opts] cmd1 [cmd1_opts] [cmd2 [cmd2_opts] ...] [skbuild_opts]
→ [-- [cmake_opts] [-- [build_tool_opts]]]
or: setup.py --help [cmd1 cmd2 ...]
or: setup.py --help-commands
or: setup.py cmd --help
```

There are four types of options:

- **setuptools options:**
 - [global_opts] cmd1 [cmd1_opts] [cmd2 [cmd2_opts] ...]
 - --help [cmd1 cmd2 ...]
 - cmd --help
- **scikit-build options:** [skbuild_opts]
- **CMake options:** [cmake_opts]
- **build tool options:** [build_tool_opts]

setuptools and scikit-build options can be passed normally, the `cmake` and `build_tool` set of options needs to be separated by `--`:

```
Arguments following a "--" are passed directly to CMake (e.g. -DMY_VAR:BOOL=TRUE).
Arguments following a second "--" are passed directly to the build tool.
```

3.3.1 setuptools options

For more details, see the [official documentation](#).

scikit-build extends the global set of setuptools options with:

New in version 0.4.0.

```
Global options:
[...]
--hide-listing      do not display list of files being included in the
                    distribution
```

New in version 0.5.0.

```
Global options:
[...]
--force-cmake      always run CMake
--skip-cmake       do not run CMake
```

3.3.2 scikit-build options

```
scikit-build options:
  --build-type      specify the CMake build type (e.g. Debug or Release)
  -G , --generator  specify the CMake build system generator
  -j N              allow N build jobs at once
```

3.3.3 CMake options

These are specific to CMake. See list of [CMake options](#).

For example:

```
-DSOME_FEATURE:BOOL=OFF
```

3.3.4 build tool options

These are specific to the underlying build tool (e.g msbuild.exe, make, ninja).

3.4 Cross-compilation

See [CMake Toolchains](#).

3.4.1 Introduction to dockcross

Note: *To be documented. See #227.*

3.4.2 Using dockcross-manylinux to generate Linux wheels

Note: *To be documented. See #227.*

3.4.3 Using dockcross-mingwpy to generate Windows wheels

Note: *To be documented. See #227.*

3.5 Examples for scikit-build developers

Note: *To be documented. See #227.*

Provide small, self-contained setup function calls for (at least) two use cases:

3.4. Cross-compilation

- when a *CMakeLists.txt* file already exists
 - when a user wants scikit-build to create a *CMakeLists.txt* file based on the user specifying some input files.
-

4.1 Introduction

By default, scikit-build looks in the project top-level directory for a file named `CMakeLists.txt`. It will then invoke `cmake` executable specifying a *generator* matching the python being used.

4.2 How to test if scikit-build is driving the compilation ?

To support the case of code base being built as both a standalone project and a python wheel, it is possible to test for the variable `SKBUILD`:

```
if(SKBUILD)
  message(STATUS "The project is built using scikit-build")
endif()
```

C Runtime, Compiler and Build System Generator

scikit-build uses sensible defaults allowing to select the C runtime matching the [official CPython](#) recommendations. It also ensures developers remain productive by selecting an alternative environment if recommended one is not available.

The table below lists the different C runtime implementations, compilers and their usual distribution mechanisms for each operating systems.

	Linux	MacOSX	Windows
C runtime	GNU C Library (glibc)	libSystem library	Microsoft C run-time library
Compiler	GNU compiler (gcc)	clang	Microsoft C/C++ Compiler (cl.exe)
Provenance	Package manager	OSX SDK within XCode	<ul style="list-style-type: none"> • Microsoft Visual Studio • Microsoft Windows SDK

5.1 Build system generator

Since scikit-build simply provides glue between *setuptools* and *CMake*, it needs to choose a *CMake* generator to configure the build system allowing to build of CPython C extensions.

The table below lists the generator supported by scikit-build:

Operating System	Linux	MacOSX	Windows
CMake Generator	<ol style="list-style-type: none">1. <i>Ninja</i>2. <i>Unix Makefiles</i>		<ol style="list-style-type: none">1. <i>Ninja</i>2. <i>Visual Studio</i>3. <i>NMake Makefiles</i>4. <i>NMake Makefiles JOM</i>

When building a project, scikit-build iteratively tries each generator (in the order listed in the table) until it finds a working one.

For more details about CMake generators, see [CMake documentation](#).

5.1.1 Ninja

- Supported platform(s): Linux, MacOSX and Windows
- If `ninja executable` is in the `PATH`, the associated generator is used to setup the project build system based on `ninja` files.

Note: Automatic parallelism

An advantage of `ninja` is that it automatically parallelizes the build based on the number of CPUs.

Note: Ninja on Windows

When `Ninja` generator is used on Windows, scikit-build will make sure the project is configured and built with the appropriate² environment (equivalent of calling `vcvarsall.bat x86` or `vcvarsall.bat amd64`).

5.1.2 Unix Makefiles

- Supported platform(s): Linux, MacOSX
- scikit-build uses this generator to generate a traditional `Makefile` based build system.

5.1.3 Visual Studio IDE

- Supported platform(s): Windows
- scikit-build uses the generator corresponding to selected version of Visual Studio and generate a `solution file` based build system.

² Implementation details: This is made possible by internally using the function `query_vcvarsall` from the `distutils.msvc9compiler` (or `distutils._msvccompiler` when visual studio \geq 2015 is used). To ensure, the environment associated with the latest compiler is properly detected, the `distutils` modules are systematically patched using `setuptools.monkey.patch_for_msvc_specialized_compiler()`.

	Architecture	
CPython Version	x86 (32-bit)	x64 (64-bit)
3.5 and above	Visual Studio 14 2015	Visual Studio 14 2008 Win64
3.3 to 3.4	Visual Studio 10 2010	Visual Studio 10 2010 Win64
2.7 to 3.2	Visual Studio 9 2008	Visual Studio 9 2008 Win64

Note: The Visual Studio generators can not be used when only *alternative environments* are installed, in that case *Ninja* or *NMake Makefiles* are used.

5.1.4 NMake Makefiles

- Supported platform(s): Windows
- scikit-build will make sure the project is configured and built with the appropriate² environment (equivalent of calling `vcvarsall.bat x86` or `vcvarsall.bat amd64`).

Note: NMake Makefiles JOM

The *NMake Makefiles JOM* generator is supported **but** it is not automatically used by scikit-build (even if `jom` executable is in the `PATH`), it always needs to be explicitly specified. For example:

```
python setup.py build -G "NMake Makefiles JOM"
```

For more details, see *scikit-build options*.

5.2 Linux

scikit-build uses the toolchain set using `CC` (and `CXX`) environment variables. If no environment variable is set, it defaults to `gcc`.

To build compliant Linux wheels, scikit-build also supports the `manylinux` platform described in [PEP-0513](#). We recommend the use of [dockcross/manylinux-x64](#) and [dockcross/manylinux-x86](#). These images are optimized for building Linux wheels using scikit-build.

5.3 MacOSX

Note: *To be documented*

See <https://github.com/MacPython/wiki/wiki/Spinning-wheels>

5.4 Windows

5.4.1 Microsoft C run-time and Visual Studio version

On windows, scikit-build looks for the version of Visual Studio matching the version of CPython being used. The selected Visual Studio version also defines which Microsoft C run-time and compiler are used:

Python version	2.7 to 3.2	3.3 to 3.4	3.5 and above
Microsoft C run-time	msvcr90.dll	msvcr100.dll	ucrtbase.dll
Compiler version	MSVC++ 9.0	MSVC++ 10.0	MSVC++ 14.0
Visual Studio version	2008	2010	2015

5.4.2 Installing compiler and Microsoft C run-time

As outlined above, installing a given version of Visual Studio will automatically install the corresponding compiler along with the Microsoft C run-time libraries.

This means that if you already have the corresponding version of Visual Studio installed, your environment is ready.

Nevertheless, since older version of Visual Studio are not available anymore, this next table references links for installing alternative environments:

Table 5.1: Download links for Windows SDK and Visual Studio.

CPython version	Download links for Windows SDK or Visual Studio
3.5 and above	<ul style="list-style-type: none">Visual C++ Build Tools 2015 or <ul style="list-style-type: none">Visual Studio 2015
3.3 to 3.4	Windows SDK for Windows 7 and .NET 4.0
2.7 to 3.2	Microsoft Visual C++ Compiler for Python 2.7

These links have been copied from the great article¹ of Steve Dower, engineer at Microsoft.

¹ How to deal with the pain of “unable to find vcvarsall.bat”

To facilitate the writing of `CMakeLists.txt` used to build CPython C/C++/Cython extensions, **scikit-build** provides the following CMake modules:

6.1 Cython

Find `cython` executable.

This module will set the following variables in your project:

CYTHON_EXECUTABLE path to the `cython` program

CYTHON_VERSION version of `cython`

CYTHON_FOUND true if the program was found

For more information on the Cython project, see <http://cython.org/>.

Cython is a language that makes writing C extensions for the Python language as easy as Python itself.

The following functions are defined:

add_cython_target

Create a custom rule to generate the source code for a Python extension module using `cython`.

add_cython_target(<Name> [<CythonInput>] [EMBED_MAIN] [C | CXX] [PY2 | PY3] [OUTPUT_VAR <OutputVar>])

<Name> is the name of the new target, and <CythonInput> is the path to a `cython` source file. Note that, despite the name, no new targets are created by this function. Instead, see `OUTPUT_VAR` for retrieving the path to the generated source for subsequent targets.

If only <Name> is provided, and it ends in the “.pyx” extension, then it is assumed to be the <CythonInput>. The name of the input without the extension is used as the target name. If only <Name> is provided, and it does not end in the “.pyx” extension, then the <CythonInput> is assumed to be <Name>.pyx.

The Cython include search path is amended with any entries found in the `INCLUDE_DIRECTORIES` property of the directory containing the `<CythonInput>` file. Use `include_directories` to add to the Cython include search path.

Options:

EMBED_MAIN Embed a `main()` function in the generated output (for stand-alone applications that initialize their own Python runtime).

C | CXX Force the generation of either a C or C++ file. By default, a C file is generated, unless the C language is not enabled for the project; in this case, a C++ file is generated by default.

PY2 | PY3 Force compilation using either Python-2 or Python-3 syntax and code semantics. By default, Python-2 syntax and semantics are used if the major version of Python found is 2. Otherwise, Python-3 syntax and semantics are used.

OUTPUT_VAR <OutputVar> Set the variable `<OutputVar>` in the parent scope to the path to the generated source file. By default, `<Name>` is used as the output variable name.

Defined variables:

<OutputVar> The path of the generated source file.

Cache variables that effect the behavior include:

CYTHON_ANNOTATE whether to create an annotated `.html` file when compiling

CYTHON_FLAGS additional flags to pass to the Cython compiler

6.1.1 Example usage

```
find_package(Cython)

# Note: In this case, either one of these arguments may be omitted; their
# value would have been inferred from that of the other.
add_cython_target(cy_code cy_code.pyx)

add_library(cy_code MODULE ${cy_code})
target_link_libraries(cy_code ...)
```

6.2 NumPy

Find the include directory for `numpy/arrayobject.h` as well as other NumPy tools like `conv-template` and `from-template`.

This module sets the following variables:

NumPy_FOUND True if NumPy was found.

NumPy_INCLUDE_DIRS The include directories needed to use NumPy.

NumPy_VERSION The version of NumPy found.

NumPy_CONV_TEMPLATE_EXECUTABLE Path to `conv-template` executable.

NumPy_FROM_TEMPLATE_EXECUTABLE Path to `from-template` executable.

The module will also explicitly define one cache variable:

`NumPy_INCLUDE_DIR`

Note: To support NumPy < v0.15.0 where `from-template` and `conv-template` are not declared as entry points, the module emulates the behavior of standalone executables by setting the corresponding variables with the path to the python interpreter and the path to the associated script. For example:

```
set (NumPy_CONV_TEMPLATE_EXECUTABLE /path/to/python /path/to/site-packages/numpy/
↳distutils/conv_template.py CACHE STRING "Command executing conv-template program"
↳FORCE)

set (NumPy_FROM_TEMPLATE_EXECUTABLE /path/to/python /path/to/site-packages/numpy/
↳distutils/from_template.py CACHE STRING "Command executing from-template program"
↳FORCE)
```

6.3 PythonExtensions

This module defines CMake functions to build Python extension modules and stand-alone executables.

The following variables are defined:

PYTHON_PREFIX	- absolute path to the current Python distribution's prefix
PYTHON_SITE_PACKAGES_DIR	- absolute path to the current Python distribution's site-packages directory
PYTHON_RELATIVE_SITE_PACKAGES_DIR	- path to the current Python distribution's site-packages directory relative to its prefix
PYTHON_SEPARATOR	- separator string for file path components. Equivalent to ``os.sep`` in Python.
PYTHON_PATH_SEPARATOR	- separator string for PATH-style environment variables. Equivalent to ``os.pathsep`` in Python.
PYTHON_EXTENSION_MODULE_SUFFIX	- suffix of the compiled module. For example, on Linux, based on environment, it could be ``.cpython-35m-x86_64-linux-gnu.so``.

The following functions are defined:

python_extension_module

For libraries meant to be used as Python extension modules, either dynamically loaded or directly linked. Amend the configuration of the library target (created using `add_library`) with additional options needed to build and use the referenced library as a Python extension module.

```
python_extension_module(<Target> [LINKED_MODULES_VAR <LinkedModVar>] [FORWARD_DECL_MODULES_VAR <ForwardDeclModVar>] [MODULE_SUFFIX <Module-Suffix>])
```

Only extension modules that are configured to be built as `MODULE` libraries can be runtime-loaded through the standard Python import mechanism. All other modules can only be included in standalone applications that are written to expect their presence. In addition to being linked against the libraries for these modules, such applications must forward declare their entry points and initialize them prior to use. To generate these forward declarations and initializations, see `python_modules_header`.

If <Target> does not refer to a target, then it is assumed to refer to an extension module that is not linked at all, but compiled along with other source files directly into an executable. Adding these modules does not cause any library

configuration modifications, and they are not added to the list of linked modules. They still must be forward declared and initialized, however, and so are added to the forward declared modules list.

Options:

LINKED_MODULES_VAR <LinkedModVar> Name of the variable referencing a list of extension modules whose libraries must be linked into the executables of any stand-alone applications that use them. By default, the global property `PY_LINKED_MODULES_LIST` is used.

FORWARD_DECL_MODULES_VAR <ForwardDeclModVar> Name of the variable referencing a list of extension modules whose entry points must be forward declared and called by any stand-alone applications that use them. By default, the global property `PY_FORWARD_DECL_MODULES_LIST` is used.

MODULE_SUFFIX <ModuleSuffix> Suffix appended to the python extension module file. The default suffix is retrieved using `sysconfig.get_config_var("SO")`, if not available, the default is then `.so` on unix and `.pyd` on windows. Setting the variable `PYTHON_EXTENSION_MODULE_SUFFIX` in the caller scope defines the value used for all extensions not having a suffix explicitly specified using `MODULE_SUFFIX` parameter.

python_standalone_executable

`python_standalone_executable(<Target>)`

For standalone executables that initialize their own Python runtime (such as when building source files that include one generated by Cython with the `-embed` option). Amend the configuration of the executable target (created using `add_executable`) with additional options needed to properly build the referenced executable.

python_modules_header

Generate a header file that contains the forward declarations and initialization routines for the given list of Python extension modules. <Name> is the logical name for the header file (no file extensions). <HeaderFilename> is the actual destination filename for the header file (e.g.: `decl_modules.h`).

```
python_modules_header(<Name> [HeaderFilename] [FORWARD_DECL_MODULES_LIST
    <ForwardDeclModList>] [HEADER_OUTPUT_VAR <HeaderOutputVar>] [IN-
    CLUDE_DIR_OUTPUT_VAR <IncludeDirOutputVar>])
```

If only <Name> is provided, and it ends in the “.h” extension, then it is assumed to be the <HeaderFilename>. The filename of the header file without the extension is used as the logical name. If only <Name> is provided, and it does not end in the “.h” extension, then the <HeaderFilename> is assumed to <Name>.h.

The exact contents of the generated header file depend on the logical <Name>. It should be set to a value that corresponds to the target application, or for the case of multiple applications, some identifier that conveys its purpose. It is featured in the generated multiple inclusion guard as well as the names of the generated initialization routines.

The generated header file includes forward declarations for all listed modules, as well as implementations for the following class of routines:

int <Name>_<Module>(void) Initializes the python extension module, <Module>. Returns an integer handle to the module.

void <Name>_LoadAllPythonModules(void) Initializes all listed python extension modules.

void CMakeLoadAllPythonModules(void); Alias for <Name>_LoadAllPythonModules whose name does not depend on <Name>. This function is excluded during preprocessing if the preprocessing macro `EXCLUDE_LOAD_ALL_FUNCTION` is defined.

void Py_Initialize_Wrapper(); Wrapper around `Py_Initialize()` that initializes all listed python extension modules. This function is excluded during preprocessing if the preprocessing macro `EXCLUDE_PY_INIT_WRAPPER` is defined. If this function is generated, then `Py_Initialize()` is re-defined to a macro that calls this function.

Options:

FORWARD_DECL_MODULES_LIST <ForwardDeclModList> List of extension modules for which to generate forward declarations of their entry points and their initializations. By default, the global property `PY_FORWARD_DECL_MODULES_LIST` is used.

HEADER_OUTPUT_VAR <HeaderOutputVar> Name of the variable to set to the path to the generated header file. By default, <Name> is used.

INCLUDE_DIR_OUTPUT_VAR <IncludeDirOutputVar> Name of the variable to set to the path to the directory containing the generated header file. By default, <Name>_INCLUDE_DIRS is used.

Defined variables:

<HeaderOutputVar> The path to the generated header file

<IncludeDirOutputVar> Directory containing the generated header file

6.3.1 Example usage

```
find_package(PythonInterp)
find_package(PythonLibs)
find_package(PythonExtensions)
find_package(Cython)
find_package(Boost COMPONENTS python)

# Simple Cython Module -- no executables
add_cython_target(_module.pyx)
add_library(_module MODULE ${_module})
python_extension_module(_module)

# Mix of Cython-generated code and C++ code using Boost Python
# Stand-alone executable -- no modules
include_directories(${Boost_INCLUDE_DIRS})
add_cython_target(main.pyx CXX EMBED_MAIN)
add_executable(main boost_python_module.cxx ${main})
target_link_libraries(main ${Boost_LIBRARIES})
python_standalone_executable(main)

# stand-alone executable with three extension modules:
# one statically linked, one dynamically linked, and one loaded at runtime
#
# Freely mixes Cython-generated code, code using Boost-Python, and
# hand-written code using the CPython API.

# module1 -- statically linked
add_cython_target(module1.pyx)
add_library(module1 STATIC ${module1})
python_extension_module(module1
    LINKED_MODULES_VAR linked_module_list
    FORWARD_DECL_MODULES_VAR fdecl_module_list)

# module2 -- dynamically linked
include_directories({Boost_INCLUDE_DIRS})
add_library(module2 SHARED boost_module2.cxx)
target_link_libraries(module2 ${Boost_LIBRARIES})
python_extension_module(module2
    LINKED_MODULES_VAR linked_module_list
    FORWARD_DECL_MODULES_VAR fdecl_module_list)
```

```
# module3 -- loaded at runtime
add_cython_target(module3a.pyx)
add_library(module1 MODULE ${module3a} module3b.cxx)
target_link_libraries(module3 ${Boost_LIBRARIES})
python_extension_module(module3
    LINKED_MODULES_VAR linked_module_list
    FORWARD_DECL_MODULES_VAR fdecl_module_list)

# application executable -- generated header file + other source files
python_modules_header(modules
    FORWARD_DECL_MODULES_LIST ${fdecl_module_list})
include_directories(${modules_INCLUDE_DIRS})

add_cython_target(mainA)
add_cython_target(mainC)
add_executable(main ${mainA} mainB.cxx ${mainC} mainD.c)

target_link_libraries(main ${linked_module_list} ${Boost_LIBRARIES})
python_standalone_executable(main)
```

6.4 F2PY

The purpose of the F2PY –Fortran to Python interface generator– project is to provide a connection between Python and Fortran languages.

F2PY is a Python package (with a command line tool `f2py` and a module `f2py2e`) that facilitates creating/building Python C/API extension modules that make it possible to call Fortran 77/90/95 external subroutines and Fortran 90/95 module subroutines as well as C functions; to access Fortran 77 COMMON blocks and Fortran 90/95 module data, including allocatable arrays from Python.

For more information on the F2PY project, see <http://www.f2py.com/>.

The following variables are defined:

F2PY_EXECUTABLE	- absolute path to the F2PY executable
-----------------	--

F2PY_VERSION_STRING	- the version of F2PY found
F2PY_VERSION_MAJOR	- the F2PY major version
F2PY_VERSION_MINOR	- the F2PY minor version
F2PY_VERSION_PATCH	- the F2PY patch version

Note: By default, the module finds the F2PY program associated with the installed NumPy package.

6.4.1 Example usage

Assuming that a package named `method` is declared in `setup.py` and that the corresponding directory containing `__init__.py` also exists, the following CMake code can be added to `method/CMakeLists.txt` to ensure the C sources associated with `cylinder_methods.f90` are generated and the corresponding module is compiled:

```
find_package(F2PY REQUIRED)

set(f2py_module_name "_cylinder_methods")
```

```

set(fortran_src_file "${CMAKE_CURRENT_SOURCE_DIR}/cylinder_methods.f90")

set(generated_module_file ${CMAKE_CURRENT_BINARY_DIR}/${f2py_module_name}${PYTHON_
↪EXTENSION_MODULE_SUFFIX})

add_custom_target(${f2py_module_name} ALL
  DEPENDS ${generated_module_file}
)

add_custom_command(
  OUTPUT ${generated_module_file}
  COMMAND ${F2PY_EXECUTABLE}
    -m ${f2py_module_name}
    -c
    ${fortran_src_file}
  WORKING_DIRECTORY ${CMAKE_CURRENT_BINARY_DIR}
)

install(FILES ${generated_module_file} DESTINATION methods)

```

Warning: Using `f2py` with `-c` argument means that `f2py` is also responsible to build the module. In that case, CMake is not used to find the compiler and configure the associated build system.

They can be included using `find_package`:

```

find_package(Cython REQUIRED)
find_package(NumPy REQUIRED)
find_package(PythonExtensions REQUIRED)
find_package(F2PY REQUIRED)

```

For more details, see the respective documentation of each modules.

Contributions are welcome, and they are greatly appreciated! Every little bit helps, and credit will always be given.

7.1 Types of Contributions

You can contribute in many ways:

7.1.1 Report Bugs

Report bugs at <https://github.com/scikit-build/scikit-build/issues>.

If you are reporting a bug, please include:

- Your operating system name and version.
- Any details about your local setup that might be helpful in troubleshooting.
- Detailed steps to reproduce the bug.

7.1.2 Fix Bugs

Look through the GitHub issues for bugs. Anything tagged with “bug” is open to whoever wants to implement it.

7.1.3 Implement Features

Look through the GitHub issues for features. Anything tagged with “feature” is open to whoever wants to implement it.

7.1.4 Write Documentation

The scikit-build project could always use more documentation. We welcome help with the official scikit-build docs, in docstrings, or even on blog posts and articles for the web.

7.1.5 Submit Feedback

The best way to send feedback is to file an issue at <https://github.com/scikit-build/scikit-build/issues>.

If you are proposing a new feature:

- Explain in detail how it would work.
- Keep the scope as narrow as possible, to make it easier to implement.
- Remember that this is a volunteer-driven project, and that contributions are welcome :)

7.2 Get Started

Ready to contribute? Here's how to set up *scikit-build* for local development.

1. Fork the *scikit-build* repo on GitHub.
2. Clone your fork locally:

```
$ git clone git@github.com:your_name_here/scikit-build.git
```

3. Install your local copy into a virtualenv. Assuming you have virtualenvwrapper installed (*pip install virtualenvwrapper*), this is how you set up your cloned fork for local development:

```
$ mkvirtualenv scikit-build
$ cd scikit-build/
$ python setup.py develop
```

4. Create a branch for local development:

```
$ git checkout -b name-of-your-bugfix-or-feature
```

Now you can make your changes locally.

5. When you're done making changes, check that your changes pass flake8 and the tests, including testing other Python versions with tox:

```
$ flake8
$ python setup.py test
$ tox
```

If needed, you can get flake8 and tox by using *pip install* to install them into your virtualenv.

6. Commit your changes and push your branch to GitHub:

```
$ git add .
$ git commit -m "Your detailed description of your changes."
$ git push origin name-of-your-bugfix-or-feature
```

7. Submit a pull request through the GitHub website.

7.3 Pull Request Guidelines

Before you submit a pull request, check that it meets these guidelines:

1. The pull request should include tests.
2. If the pull request adds functionality, the docs should be updated. Put your new functionality into a function with a docstring, and add the feature to the list in *README.rst*.
3. The pull request should work for Python 2.7, and 3.3, 3.4, 3.5 and PyPy. Check https://travis-ci.org/scikit-build/scikit-build/pull_requests and make sure that the tests pass for all supported Python versions.

7.4 Tips

To run a subset of tests:

```
$ pytest tests/test_skbuild.py
```

8.1 Controlling CMake using scikit-build

You can drive CMake directly using scikit-build:

```
""" Use scikit-build's `cmaker` to control CMake configuration and build.

1. Use `cmaker` to define an object that provides convenient access to
   CMake's configure and build functionality.

2. Use defined object, `maker`, to call `configure()` to read the
   `CMakeLists.txt` file in the current directory and generate a Makefile,
   Visual Studio solution, or whatever is appropriate for your platform.

3. Call `make()` on the object to execute the build with the
   appropriate build tool and perform installation to the local directory.
"""
from skbuild import cmaker
maker = cmaker.CMaker()

maker.configure()

maker.make()
```

See `skbuild.cmaker.CMaker` for more details.

8.2 Internal API

8.2.1 skbuild

skbuild package

scikit-build is an improved build system generator for CPython C extensions.

This module provides the *glue* between the setuptools Python module and CMake.

`skbuild.setup(*args, **kw)`

This function wraps `setup()` so that we can run `cmake`, `make`, CMake build, then proceed as usual with setuptools, appending the CMake-generated output as necessary.

Subpackages

skbuild.command package

Collection of objects allowing to customize behavior of standard distutils and setuptools commands.

class `skbuild.command.set_build_base_mixin`

Bases: `object`

Mixin allowing to override distutils and setuptools commands.

finalize_options (`*args, **kwargs`)

Override built-in function and set a new *build_base*.

Submodules

skbuild.command.bdist module

This module defines custom implementation of `bdist` setuptools command.

class `skbuild.command.bdist.bdist` (`dist, **kw`)

Bases: `skbuild.command.set_build_base_mixin, skbuild.utils.NewStyleClass`

Custom implementation of `bdist` setuptools command.

skbuild.command.bdist_wheel module

This module defines custom implementation of `bdist_wheel` setuptools command.

class `skbuild.command.bdist_wheel.bdist_wheel` (`dist, **kw`)

Bases: `skbuild.command.set_build_base_mixin, skbuild.utils.NewStyleClass`

Custom implementation of `bdist_wheel` setuptools command.

run (`*args, **kwargs`)

skbuild.command.build module

This module defines custom implementation of `build` setuptools command.

```
class skbuild.command.build.build (dist, **kw)
    Bases: skbuild.command.set_build_base_mixin, skbuild.utils.NewStyleClass
    Custom implementation of build setuptools command.
```

skbuild.command.build_py module

This module defines custom implementation of `build_py` setuptools command.

```
class skbuild.command.build_py.build_py (dist, **kw)
    Bases: skbuild.command.set_build_base_mixin, skbuild.utils.NewStyleClass
    Custom implementation of install_data setuptools command.

build_module (module, module_file, package)
    Handle -hide-listing option.

    Increments outfiles_count.

find_modules ()
    Finds individually-specified Python modules, ie. those listed by module name in 'self.py_modules'. Returns a list of tuples (package, module_base, filename): 'package' is a tuple of the path through package-space to the module; 'module_base' is the bare (no packages, no dots) module name, and 'filename' is the path to the ".py" file (relative to the distribution root) that implements the module.

initialize_options ()
    Handle -hide-listing option.

    Initializes outfiles_count.

run (*args, **kwargs)
    Handle -hide-listing option.

    Display number of copied files. It corresponds to the value of outfiles_count.
```

skbuild.command.clean module

This module defines custom implementation of `clean` setuptools command.

```
class skbuild.command.clean.clean (dist, **kw)
    Bases: skbuild.command.set_build_base_mixin, skbuild.utils.NewStyleClass
    Custom implementation of clean setuptools command.

run ()
    After calling the super class implementation, this function removes the directories specific to scikit-build.
```

skbuild.command.egg_info module

This module defines custom implementation of `egg_info` setuptools command.

```
class skbuild.command.egg_info.egg_info (dist, **kw)
    Bases: skbuild.command.set_build_base_mixin, skbuild.utils.NewStyleClass
    Custom implementation of egg_info setuptools command.
```

```
finalize_options (*args, **kwargs)
```

skbuild.command.generate_source_manifest module

This module defines custom `generate_source_manifest` setuptools command.

```
class skbuild.command.generate_source_manifest.generate_source_manifest (dist)
    Bases: skbuild.command.set_build_base_mixin, skbuild.utils.NewStyleClass
```

Custom setuptools command generating a *MANIFEST* file if not already provided.

```
description = 'generate source MANIFEST'
```

```
finalize_options (*args, **kwargs)
```

Set final values for all the options that this command supports.

```
initialize_options ()
```

Set default values for all the options that this command supports.

```
run ()
```

If neither a *MANIFEST*, nor a *MANIFEST.in* file is provided, and we are in a git repo, try to create a *MANIFEST* file from the output of `git ls-tree --name-only -r HEAD`.

We need a reliable way to tell if an existing *MANIFEST* file is one we've generated. `distutils` already uses a first-line comment to tell if the *MANIFEST* file was generated from *MANIFEST.in*, so we use a dummy file, `_skbuild_MANIFEST`, to avoid confusing `distutils`.

skbuild.command.install module

This module defines custom implementation of `install` setuptools command.

```
class skbuild.command.install.install (dist, **kw)
```

Bases: *skbuild.command.set_build_base_mixin*, *skbuild.utils.NewStyleClass*

Custom implementation of `install` setuptools command.

```
finalize_options (*args, **kwargs)
```

Ensure that if the distribution is non-pure, all modules are installed in `self.install_platlib`.

Note: `setuptools.dist.Distribution.has_ext_modules()` is overridden in `setuptools_wrap.setup()`.

skbuild.command.install_lib module

This module defines custom implementation of `install_lib` setuptools command.

```
class skbuild.command.install_lib.install_lib (dist, **kw)
```

Bases: *skbuild.command.set_build_base_mixin*, *skbuild.utils.NewStyleClass*

Custom implementation of `install_data` setuptools command.

```
install ()
```

Handle `--hide-listing` option.

skbuild.command.install_scripts module

This module defines custom implementation of `install_scripts` setuptools command.

class `skbuild.command.install_scripts.install_scripts` (*dist*, ***kw*)
Bases: `skbuild.command.set_build_base_mixin`, `skbuild.utils.NewStyleClass`

Custom implementation of `install_data` setuptools command.

run (**args*, ***kwargs*)
Handle `-hide-listing` option.

skbuild.command.sdist module

This module defines custom implementation of `sdist` setuptools command.

class `skbuild.command.sdist.sdist` (*dist*, ***kw*)
Bases: `skbuild.command.set_build_base_mixin`, `skbuild.utils.NewStyleClass`

Custom implementation of `sdist` setuptools command.

make_archive (*base_name*, *_format*, *root_dir=None*, *base_dir=None*, *owner=None*, *group=None*)
Handle `-hide-listing` option.

make_release_tree (*base_dir*, *files*)
Handle `-hide-listing` option.

run (**args*, ***kwargs*)
Force `egg_info.egg_info` command to run.

skbuild.platform_specifics package

This package provides `get_platform()` allowing to get an instance of `abstract.CMakePlatform` matching the current platform.

class `skbuild.platform_specifics.CMakeGenerator` (*name*, *env=None*)
Bases: `object`

Represents a CMake generator.

__init__ (*name*, *env=None*)
Instantiate a generator object with the given name.

By default, `os.environ` is associated with the generator. Dictionary passed as `env` parameter will be merged with `os.environ`. If an environment variable is set in both `os.environ` and `env`, the variable in `env` is used.

name
Name of CMake generator.

`skbuild.platform_specifics.get_platform()`
Return an instance of `abstract.CMakePlatform` corresponding to the current platform.

Submodules

skbuild.platform_specifics.abstract module

This module defines objects useful to discover which CMake generator is supported on the current platform.

class `skbuild.platform_specifics.abstract.CMakeGenerator` (*name, env=None*)
Bases: `object`

Represents a CMake generator.

__init__ (*name, env=None*)

Instantiate a generator object with the given name.

By default, `os.environ` is associated with the generator. Dictionary passed as `env` parameter will be merged with `os.environ`. If an environment variable is set in both `os.environ` and `env`, the variable in `env` is used.

name

Name of CMake generator.

class `skbuild.platform_specifics.abstract.CMakePlatform`

Bases: `object`

This class encapsulates the logic allowing to get the identifier of a working CMake generator.

Derived class should at least set `default_generators`.

static cleanup_test ()

Delete test project directory.

static compile_test_cmakelist (**args, **kws*)

Attempt to configure the test project with each `CMakeGenerator` from `candidate_generators`.

Only cmake arguments starting with `-DCMAKE_` are used to configure the test project.

The function returns the first generator allowing to successfully configure the test project using `cmake_exe_path`.

default_generators

List of generators considered by `get_best_generator()`.

generator_installation_help

Return message guiding the user for installing a valid toolchain.

get_best_generator (*generator_name=None, languages=('CXX', 'C'), cleanup=True, cmake_args=()*)

Loop over generators to find one that works by configuring and compiling a test project.

Parameters

- **generator_name** (*string or None*) – If provided, uses only provided generator, instead of trying `default_generators`.
- **languages** (*tuple*) – The languages you'll need for your project, in terms that CMake recognizes.
- **cleanup** (*bool*) – If True, cleans up temporary folder used to test generators. Set to False for debugging to see CMake's output files.
- **cmake_args** (*tuple*) – List of CMake arguments to use when configuring the test project. Only arguments starting with `-DCMAKE_` are used.

Returns CMake Generator object

Return type *CMakeGenerator* or None

Raises *skbuild.exceptions.SKBuildGeneratorNotFoundError* –

get_cmake_exe_path()

Override this method with additional logic where necessary if CMake is not on PATH.

static write_test_cmakelist(languages)

Write a minimal CMakeLists.txt useful to check if the requested languages are supported.

skbuild.platform_specifics.bsd module

This module defines object specific to BSD platform.

class *skbuild.platform_specifics.bsd.BSDPlatform*

Bases: *skbuild.platform_specifics.unix.UnixPlatform*

BSD implementation of *abstract.CMakePlatform*.

skbuild.platform_specifics.linux module

This module defines object specific to Linux platform.

class *skbuild.platform_specifics.linux.LinuxPlatform*

Bases: *skbuild.platform_specifics.unix.UnixPlatform*

Linux implementation of *abstract.CMakePlatform*

static build_essential_install_cmd()

Return a tuple of the form (distribution_name, cmd).

cmd is the command allowing to install the build tools in the current Linux distribution. It set to an empty string if the command is not known.

distribution_name is the name of the current distribution. It is set to an empty string if the distribution could not be determined.

generator_installation_help

Return message guiding the user for installing a valid toolchain.

skbuild.platform_specifics.osx module

This module defines object specific to OSX platform.

class *skbuild.platform_specifics.osx.OSXPlatform*

Bases: *skbuild.platform_specifics.unix.UnixPlatform*

OSX implementation of *abstract.CMakePlatform*.

generator_installation_help

Return message guiding the user for installing a valid toolchain.

skbuild.platform_specifics.platform_factory module

This modules implements the logic allowing to instantiate the expected *abstract.CMakePlatform*.

skbuild.platform_specifics.platform_factory.get_platform()

Return an instance of *abstract.CMakePlatform* corresponding to the current platform.

skbuild.platform_specifics.unix module

This module defines object specific to Unix platform.

class `skbuild.platform_specifics.unix.UnixPlatform`
Bases: `skbuild.platform_specifics.abstract.CMakePlatform`
Unix implementation of `abstract.CMakePlatform`.

skbuild.platform_specifics.windows module

This module defines object specific to Windows platform.

class `skbuild.platform_specifics.windows.CMakeVisualStudioCommandLineGenerator` (*name*, *year*)

Bases: `skbuild.platform_specifics.abstract.CMakeGenerator`

Represents a command-line CMake generator initialized with a specific *Visual Studio* environment.

`__init__` (*name*, *year*)

Instantiate CMake command-line generator.

The generator name can be values like *Ninja*, *NMake Makefiles* or *NMake Makefiles JOM*.

The *year* defines the *Visual Studio* environment associated with the generator. See [VS_YEAR_TO_VERSION](#).

The platform (32-bit or 64-bit) is automatically selected based on the value of `platform.architecture()` [0].

class `skbuild.platform_specifics.windows.CMakeVisualStudioIDEGenerator` (*year*)

Bases: `skbuild.platform_specifics.abstract.CMakeGenerator`

Represents a Visual Studio CMake generator.

`__init__` (*year*)

Instantiate a generator object with its name set to the *Visual Studio* generator associated with the given *year* (see [VS_YEAR_TO_VERSION](#)) and the current platform (32-bit or 64-bit).

`skbuild.platform_specifics.windows.VS_YEAR_TO_VERSION = {'2015': 14, '2008': 9, '2010': 10}`
Describes the version of *Visual Studio* supported by `CMakeVisualStudioIDEGenerator` and `CMakeVisualStudioCommandLineGenerator`.

The different version are identified by their year.

class `skbuild.platform_specifics.windows.WindowsPlatform`

Bases: `skbuild.platform_specifics.abstract.CMakePlatform`

Windows implementation of `abstract.CMakePlatform`.

`generator_installation_help`

Return message guiding the user for installing a valid toolchain.

skbuild.utils package

This module defines functions generally useful in scikit-build.

class `skbuild.utils.ContextDecorator` (***kwargs*)

Bases: `object`

A base class or mixin that enables context managers to work as decorators.

class `skbuild.utils.PythonModuleFinder` (*packages, package_dir, py_modules, alternative_build_base=None*)

Bases: `skbuild.utils.NewStyleClass`

Convenience class to search for python modules.

This class is based on `distutils.command.build_py.build_by` and provides a specialized version of `find_all_modules()`.

check_module (*module, module_file*)

Return True if `module_file` belongs to `module`.

find_all_modules (*project_dir=None*)

Compute the list of all modules that would be built by project located in current directory, whether they are specified one-module-at-a-time `py_modules` or by whole packages `packages`.

By default, the function will search for modules in the current directory. Specifying `project_dir` parameter allow to change this.

Return a list of tuples (`package, module, module_file`).

find_package_modules (*package, package_dir*)

Temporally prepend the `alternative_build_base` to `module_file`. Doing so will ensure modules can also be found in other location (e.g `skbuild.constants.CMAKE_INSTALL_DIR`).

`skbuild.utils.distribution_hide_listing` (**args, **kws*)

Given a `distribution`, this context manager temporarily sets `distutils` threshold to `WARN` if `--hide-listing` argument was provided.

It yields True if `--hide-listing` argument was provided.

`skbuild.utils.mkdir_p` (*path*)

Ensure directory `path` exists. If needed, parent directories are created.

Adapted from <http://stackoverflow.com/a/600612/1539918>

`skbuild.utils.new_style` (*klass*)

`distutils/setuputils` command classes are old-style classes, which won't work with mixins.

To work around this limitation, we dynamically convert them to new style classes by creating a new class that inherits from them and also `<object>`. This ensures that `<object>` is always at the end of the MRO, even after being mixed in with other classes.

class `skbuild.utils.push_dir` (*directory=None, make_directory=False*)

Bases: `skbuild.utils.ContextDecorator`

Context manager to change current directory.

`skbuild.utils.to_platform_path` (*path*)

Return a version of `path` where all separator are `os.sep`

`skbuild.utils.to_unix_path` (*path*)

Return a version of `path` where all separator are `/`

Submodules

skbuild.cmaker module

This module provides an interface for invoking CMake executable.

class `skbuild.cmaker.CMaker`

Bases: `object`

Interface to CMake executable.

static `check_for_bad_installs()`

This function tries to catch files that are meant to be installed outside the project root before they are actually installed.

Indeed, we can not wait for the manifest, so we try to extract the information (install destination) from the CMake build files `*.cmake` found in `CMAKE_BUILD_DIR`.

It raises `SKBuildError` if it found install destination outside of `CMAKE_INSTALL_DIR`.

configure (`clargs=()`, `generator_name=None`, `cmake_source_dir='.'`, `cmake_install_dir=""`,
`cleanup=True`)

Calls `cmake` to generate the Makefile/VIS Solution/XCode project.

clargs: tuple List of command line arguments to pass to `cmake` executable.

generator_name: string The string representing the CMake generator to use. If `None`, uses defaults for your platform.

cmake_source_dir: string Path to source tree containing a `CMakeLists.txt`

cmake_install_dir: string Relative directory to append to `skbuild.constants.CMAKE_INSTALL_DIR`.

cleanup: bool If `True`, cleans up temporary folder used to test generators. Set to `False` for debugging to see CMake's output files.

Return a mapping of the environment associated with the selected `skbuild.platform_specifics.abstract.CMakeGenerator`.

static `get_python_include_dir(python_version)`

Get include directory associated with the current python interpreter.

static `get_python_library(python_version)`

Get path to the python library associated with the current python interpreter.

static `get_python_version()`

Get version associated with the current python interpreter.

install()

Returns a list of file paths to install via `setuptools` that is compatible with the `data_files` keyword argument.

make (`clargs=()`, `config='Release'`, `source_dir='.'`, `env=None`)

Calls the system-specific `make` program to compile code.

`skbuild.cmaker.pop_arg(arg, args, default=None)`

Pops an argument `arg` from an argument list `args` and returns the new list and the value of the argument if present and a default otherwise.

skbuild.constants module

This module defines constants commonly used in `scikit-build`.

skbuild.exceptions module

This module defines exceptions commonly used in `scikit-build`.

exception `skbuild.exceptions.SKBuildError`

Bases: `exceptions.RuntimeError`

Exception raised when an error occurs while configuring or building a project.

exception `skbuild.exceptions.SKBuildGeneratorNotFoundError`

Bases: `skbuild.exceptions.SKBuildError`

Exception raised when no suitable generator is found for the current platform.

skbuild.setuptools_wrap module

This module provides functionality for wrapping key infrastructure components from distutils and setuptools.

`skbuild.setuptools_wrap.create_skbuild_argparser()`

Create and return a scikit-build argument parser.

`skbuild.setuptools_wrap.parse_args()`

This function parses the command-line arguments `sys.argv` and returns the tuple `(setuptools_args, cmake_args, build_tool_args)` where each element corresponds to a set of arguments separated by `--`.

`skbuild.setuptools_wrap.parse_skbuild_args(args, cmake_args, build_tool_args)`

Parse arguments in the scikit-build argument set. Convert specified arguments to proper format and append to `cmake_args` and `build_tool_args`. Returns remaining arguments.

`skbuild.setuptools_wrap.setup(*args, **kw)`

This function wraps `setup()` so that we can run `cmake`, `make`, `CMake` build, then proceed as usual with `setuptools`, appending the `CMake`-generated output as necessary.

`skbuild.setuptools_wrap.strip_package(package_parts, module_file)`

Given `package_parts` (e.g. `['foo', 'bar']`) and a `module_file` (e.g. `foo/bar/jaz/rock/roll.py`), starting from the left, this function will strip the parts of the path matching the package parts and return a new string (e.g. `jaz/rock/roll.py`).

The function will work as expected for either Windows or Unix-style `module_file` and this independently of the platform.

8.3 Internal CMake Modules

8.3.1 targetLinkLibrariesWithDynamicLookup

Public Functions

The following functions are defined:

target_link_libraries_with_dynamic_lookup

```
target_link_libraries_with_dynamic_lookup(<Target> [<Libraries>])
```

Useful to “weakly” link a loadable module. For example, it should be used when compiling a loadable module when the symbols should be resolve from the run-time environment where the module is loaded, and not a specific system library.

Like proper linking, except that the given `<Libraries>` are not necessarily linked. Instead, the `<Target>` is produced in a manner that allows for symbols unresolved within it to be resolved at runtime, presumably by the given `<Libraries>`. If such a target can be produced, the provided `<Libraries>` are not actually linked.

It links a library to a target such that the symbols are resolved at run-time not link-time.

The linker is checked to see if it supports undefined symbols when linking a shared library. If it does then the library is not linked when specified with this function.

On platforms that do not support weak-linking, this function works just like `target_link_libraries`.

Note: For OSX it uses `undefined dynamic_lookup`. This is similar to using `-shared` on Linux where undefined symbols are ignored.

For more details, see [blog](#) from Tim D. Smith.

`check_dynamic_lookup`

Check if the linker requires a command line flag to allow leaving symbols unresolved when producing a target of type `<TargetType>` that is weakly-linked against a dependency of type `<LibType>`.

<TargetType> can be one of “STATIC”, “SHARED”, “MODULE”, or “EXE”.

<LibType> can be one of “STATIC”, “SHARED”, or “MODULE”.

Long signature:

```
check_dynamic_lookup(<TargetType>
                    <LibType>
                    <ResultVar>
                    [<LinkFlagsVar>])
```

Short signature:

```
check_dynamic_lookup(<ResultVar>) # <TargetType> set to "MODULE"
                                # <LibType> set to "SHARED"
```

The result is cached between invocations and recomputed only when the value of CMake’s linker flag list changes; `CMAKE_STATIC_LINKER_FLAGS` if `<TargetType>` is “STATIC”, and `CMAKE_SHARED_LINKER_FLAGS` otherwise.

Defined variables:

<ResultVar> Whether the current C toolchain supports weak-linking for target binaries of type `<TargetType>` that are weakly-linked against a dependency target of type `<LibType>`.

<LinkFlagsVar> List of flags to add to the linker command to produce a working target binary of type `<TargetType>` that is weakly-linked against a dependency target of type `<LibType>`.

HAS_DYNAMIC_LOOKUP_<TargetType>_<LibType> Cached, global alias for `<ResultVar>`

DYNAMIC_LOOKUP_FLAGS_<TargetType>_<LibType> Cached, global alias for `<LinkFlagsVar>`

Private Functions

The following private functions are defined:

Warning: These functions are not part of the scikit-build API. They exist purely as an implementation detail and may change from version to version without notice, or even be removed.

We mean it.

`_get_target_type`

```
_get_target_type(<ResultVar> <Target>)
```

Shorthand for querying an abbreviated version of the target type of the given `<Target>`.

`<ResultVar>` is set to:

- “STATIC” for a `STATIC_LIBRARY`,
- “SHARED” for a `SHARED_LIBRARY`,
- “MODULE” for a `MODULE_LIBRARY`,
- and “EXE” for an `EXECUTABLE`.

Defined variables:

`<ResultVar>` The abbreviated version of the `<Target>`’s type.

`_test_weak_link_project`

```
_test_weak_link_project (<TargetType>
                        <LibType>
                        <ResultVar>
                        <LinkFlagsVar>)
```

Attempt to compile and run a test project where a target of type `<TargetType>` is weakly-linked against a dependency of type `<LibType>`:

- `<TargetType>` can be one of “STATIC”, “SHARED”, “MODULE”, or “EXE”.
- `<LibType>` can be one of “STATIC”, “SHARED”, or “MODULE”.

Defined variables:

`<ResultVar>` Whether the current C toolchain can produce a working target binary of type `<TargetType>` that is weakly-linked against a dependency target of type `<LibType>`.

`<LinkFlagsVar>` List of flags to add to the linker command to produce a working target binary of type `<TargetType>` that is weakly-linked against a dependency target of type `<LibType>`.

CHAPTER 9

Credits

Please see the GitHub project page at <https://github.com/scikit-build/scikit-build/graphs/contributors>

CHAPTER 10

History

PyCMake was created at SciPy 2014 in response to general difficulties building C++ and Fortran based Python extensions across platforms. It was renamed to “scikit-build” in 2016.

This is the list of changes to scikit-build between each release. For full details, see the commit logs at <http://github.com/scikit-build/scikit-build>

11.1 Next Release

11.1.1 New Features

- Add CMake module *F2PY* useful to find the `f2py` executable for building Python extensions with Fortran. Thanks to @xoviat for moving forward with the integration. Concept for the module comes from the work of @scopatz done in PyNE project. See #273.
- Update CMake module *NumPy* setting variables `NumPy_CONV_TEMPLATE_EXECUTABLE` and `NumPy_FROM_TEMPLATE_EXECUTABLE`. Thanks @xoviat for the contribution. See #278.
- Use `_skbuild/platform-X.Y` instead of `_skbuild` to build package. This allows to have a different build directory for each python version. Thanks @isuruf for the suggestion and @xoviat for contributing the feature. See #283.

11.1.2 Bug fixes

- Fix support of `--hide-listing` when building wheel.
- CMake module *Cython*: Fix escaping of spaces associated with `CYTHON_FLAGS` when provided as command line arguments to the cython executable through CMake cache entries. See #265 fixed by @neok-m4700.
- Ensure package data files specified in the `setup()` function using `package_data` keyword are packaged and installed.

11.1.3 Tests

- Speedup execution of tests that do not require any CMake language enabled. This is achieved by (1) introducing the test project `hello-no-language`, (2) updating test utility functions `execute_setup_py` and `project_setup_py_test` to accept the optional parameter `disable_languages_test` allowing to skip unneeded compiler detection in test project used to verify that the selected CMake generator works as expected, and (3) updating relevant tests to use the new test project and parameters.

Overall testing time on all continuous integration services was reduced:

- AppVeyor:
 - * from **~16 to ~7** minutes for 64 and 32-bit Python 2.7 tests done using Visual Studio Express 2008
 - * from more than **2 hours to ~50 minutes** for 64 and 32-bit Python 3.5 tests done using Visual Studio 2015. Improvement specific to Python 3.x were obtained by caching the results of slow calls to `distutils.msvc9compiler.query_vcvarsall` (for Python 3.3 and 3.4) and `distutils._msvccompiler._get_vc_env` (for Python 3.5 and above). These functions were called multiple times to create the list of `skbuild.platform_specifics.windows.CMakeVisualStudioCommandLineGenerator` used in `skbuild.platform_specifics.windows.WindowsPlatform`.
- CircleCI: from **~7 to ~5** minutes.
- TravisCI: from **~21 to ~10** minutes.
- Update maximum line length specified in flake8 settings from 80 to 120 characters.

11.1.4 Documentation

- Improve internal API documentation:
 - `skbuild.platform_specifics.windows`
 - `skbuild.command`
 - `skbuild.command.generate_source_manifest`
 - `skbuild.utils`

11.1.5 Cleanups

- Fix miscellaneous pylint warnings.

11.2 Scikit-build 0.6.1

11.2.1 Bug fixes

- Ensure CMake arguments passed to scikit-build and starting with `-DCMAKE_*` are passed to the test project allowing to determine which generator to use. For example, this ensures that arguments like `-DCMAKE_MAKE_PROGRAM:FILEPATH=/path/to/program` are passed. See #256.

11.2.2 Documentation

- Update *How to Make a Release* section including instructions to update `README.rst` with up-to-date pypi download statistics based on Google big table.

11.3 Scikit-build 0.6.0

11.3.1 New features

- Improve `py_modules` support: Python modules generated by CMake are now properly included in binary distribution.
- Improve developer mode support for `py_modules` generated by CMake.

11.3.2 Bug fixes

- Do not implicitly install python modules when the beginning of their name match a package explicitly listed. For example, if a project has a package `foo/__init__.py` and a module `fooConfig.py`, and only package `foo` was listed in `setup.py`, `fooConfig.py` is not installed anymore.
- CMake module *targetLinkLibrariesWithDynamicLookup*: Fix the caching of *dynamic lookup* variables. See #240 fixed by @blowekamp.

11.3.3 Requirements

- wheel: As suggested by @thewtex, unpinning version of the package by requiring `>=0.29.0` instead of `==0.29.0` will avoid uninstalling a newer version of wheel package on up-to-date system.

11.3.4 Documentation

- Add a command line *CMake Options* section to *Usage*.
- Fix *table* listing *Visual Studio IDE* version and corresponding with *CPython version* in *C Runtime, Compiler and Build System Generator*.
- Improve *How to Make a Release* section.

11.3.5 Tests

- Extend `test_hello`, `test_setup`, and `test_sdist_hide_listing` to (1) check if python modules are packaged into source and wheel distributions and (2) check if python modules are copied into the source tree when developer mode is enabled.

11.3.6 Internal API

- Fix `skbuild.setuptools_wrap.strip_package()` to handle empty package.
- Teach `skbuild.command.build_py.build_py.find_modules()` function to look for *py_module* file in `CMAKE_INSTALL_DIR`.
- Teach `skbuild.utils.PythonModuleFinder` to search for *python module* in the CMake install tree.

- Update `skbuild.setuptools_wrap._consolidate()` to copy file into the CMake tree only if it exists.
- Update `skbuild.setuptools_wrap._copy_file()` to create directory only if there is one associated with the destination file.

11.4 Scikit-build 0.5.1

11.4.1 Bug fixes

- Ensure file copied in “develop” mode have “mode bits” maintained.

11.5 Scikit-build 0.5.0

11.5.1 New features

- Improve user experience by running CMake only if needed. See [#207](#)
- Add support for `cmake_with_sdist` setup keyword argument.
- Add support for `--force-cmake` and `--skip-cmake` global *setup command-line options*.
- scikit-build conda-forge recipe added by [@isuruf](#). See [conda-forge/staged-recipes#1989](#)
- Add support for [development mode](#). ([#187](#)).
- Improved *C Runtime, Compiler and Build System Generator* selection:
- If available, uses *Ninja* build system generator on all platforms. An advantage is that ninja automatically parallelizes the build based on the number of CPUs.
- Automatically set the expected *Visual Studio* environment when *Ninja* or *NMake Makefiles* generators are used.
- Support [Microsoft Visual C++ Compiler for Python 2.7](#). See [#216](#).
- Prompt for user to install the required compiler if it is not available. See [#27](#).
- Improve `targetLinkLibrariesWithDynamicLookup` CMake Module extending the API of `check_dynamic_lookup` function:
- Update long signature: `<LinkFlagsVar>` is now optional
- Add support for short signature: `check_dynamic_lookup(<ResultVar>)`. See [SimpleITK/SimpleITK#80](#).

11.5.2 Bug fixes

- Fix scikit-build source distribution and add test. See [#214](#) Thanks [@isuruf](#) for reporting the issue.
- Support building extension within a virtualenv on windows. See [#119](#).

11.5.3 Documentation

- add *C Runtime, Compiler and Build System Generator* section
- add *Release Notes* section
- allow github issues and users to easily be referenced using `:issue:`XY`` and `:user:`username`` markups. This functionality is enabled by the `sphinx-issue` sphinx extension
- `make_a_release`: Ensure uploaded distributions are signed
- usage:
- Add empty cross-compilation / wheels building sections
- Add *Why should I use scikit-build ?*
- Add *Setup options* section
- hacking:
- Add *Internal API* section generated using `sphinx-apidoc`.
- Add *Internal CMake Modules* to document `targetLinkLibrariesWithDynamicLookup` CMake module.

11.5.4 Requirements

- `setuptools`: As suggested by [@mivade](#) in [#212](#), remove the hard requirement for `==28.8.0` and require version `>= 28.0.0`. This allows to “play” nicely with conda where it is problematic to update the version of `setuptools`. See [pypa/pip#2751](#) and [ContinuumIO/anaconda-issues#542](#).

11.5.5 Tests

- Improve “push_dir” tests to not rely on build directory name. Thanks [@isuruf](#) for reporting the issue.
- `travis/install_pyenv`: Improve MacOSX build time updating `scikit-ci-addons`
- Add `get_cmakecache_variables` utility function.

11.5.6 Internal API

- `skbuild.cmaker.CMaker.configure()`: Change parameter name from `generator_id` to `generator_name`. This is consistent with how generator are identified in [CMake documentation](#). This change breaks backward compatibility.
- `skbuild.platform_specifics.abstract.CMakePlatform.get_best_generator()`: Change parameter name from `generator` to `generator_name`. Note that this function is also directly importable from `skbuild.platform_specifics`. This change breaks backward compatibility.
- `skbuild.platform_specifics.abstract.CMakeGenerator`: This class allows to handle generators as sophisticated object instead of simple string. This is done anticipating the support for `CMAKE_GENERATOR_PLATFORM` and `CMAKE_GENERATOR_TOOLSET`. Note also that the class is directly importable from `skbuild.platform_specifics` and is now returned by `skbuild.platform_specifics.get_best_generator()`. This change breaks backward compatibility.

11.5.7 Cleanups

- `appveyor.yml`:
- Remove unused “`on_failure: event logging`” and “`notifications: GitHubPullRequest`”
- Remove unused `SKIP` env variable

11.6 Scikit-build 0.4.0

11.6.1 New features

- Add support for `--hide-listing` option
- allow to build distributions without displaying files being included
- useful when building large project on Continuous Integration service limiting the amount of log produced by the build
- CMake module: `skbuild/resources/cmake/FindPythonExtensions.cmake`
- Function `python_extension_module`: add support for `module suffix`

11.6.2 Bug fixes

- Do not package python modules under “`purelib`” dir in non-pure wheel
- CMake module: `skbuild/resources/cmake/targetLinkLibrariesWithDynamicLookup.cmake`:
- Fix the logic checking for cross-compilation (the regression was introduced by [#51](#) and [#47](#))
- It configure the text project setting `CMAKE_ENABLE_EXPORTS` to ON. Doing so ensure the executable compiled in the test exports symbols (if supported by the underlying platform)

11.6.3 Docs

- Add `short note` explaining how to include scikit-build CMake module
- Move “Controlling CMake using scikit-build” into a “hacking” section
- Add initial version of “`extension_build_system`” documentation

11.6.4 Tests

- `tests/samples`: Simplify project removing unneeded install rules and file copy
- Simplify continuous integration
- use `scikit-ci` and `scikit-ci-addons`
- speed up build setting up caching
- Makefile:
- Fix `coverage` target

- Add *docs-only* target allowing to regenerate the Sphinx documentation without opening a new page in the browser.

11.7 Scikit-build 0.3.0

11.7.1 New features

- Improve support for “pure”, “CMake” and “hybrid” python package
- a “pure” package is a python package that have all files living in the project source tree
- an “hybrid” package is a python package that have some files living in the project source tree and some files installed by CMake
- a “CMake” package is a python package that is fully generated and installed by CMake without any of his files existing in the source tree
- Add support for source distribution. See #84
- Add support for setup arguments specific to scikit-build:
- `cmake_args`: additional option passed to CMake
- `cmake_install_dir`: relative directory where the CMake project being built should be installed
- `cmake_source_dir`: location of the CMake project
- Add CMake module `FindNumPy.cmake`
- Automatically set `package_dir` to reasonable defaults
- Support building project without `CMakeLists.txt`

11.7.2 Bug fixes

- Fix dispatch of arguments to `setuptools`, CMake and build tool. See #118
- Force binary wheel generation. See #106
- Fix support for `py_modules` (6716723)
- Do not raise error if calling “clean” command twice

11.7.3 Documentation

- Improvement of documentation published on <http://scikit-build.readthedocs.io/en/latest/>
- Add docstrings for most of the modules, classes and functions

11.7.4 Tests

- Ensure each test run in a dedicated temporary directory
- Add tests to raise coverage from 70% to 91%
- Refactor CI testing infrastructure introducing CI drivers written in python for AppVeyor, CircleCI and TravisCI
- Switch from `nose` to `py.test`

- Relocate sample projects into a dedicated home: <https://github.com/scikit-build/scikit-build-sample-projects>

11.7.5 Cleanups

- Refactor commands introducing `set_build_base_mixin` and `new_style`
- Remove unused code

How to Make a Release

A core developer should use the following steps to create a release *X.Y.Z* of **scikit-build**.

0. Configure `~/pypirc` as described [here](#).
1. Make sure that all CI tests are passing.
2. Update version numbers and download count:
 - in `setup.py` and `skbuild/__init__.py`
 - in `CHANGES.rst` by changing `Next Release` section header with `Scikit-build X.Y.Z`.
 - run [this big table query](#) and update the pypi download count in `README.rst`. To learn more about `pypi-stats`, see [How to get PyPI download statistics](#).
3. Commit the changes using title `scikit-build X.Y.Z`.
3. Create the source tarball and binary wheels:

```
git checkout master
git fetch upstream
git reset --hard upstream/master
rm -rf dist/
python setup.py sdist bdist_wheel
```

4. Upload the packages to the testing PyPI instance:

```
twine upload --sign -r pypitest dist/*
```

5. Check the [PyPI testing package page](#).
6. Tag the release. Requires a GPG key with signatures. For version *X.Y.Z*:

```
git tag -s -m "scikit-build X.Y.Z" X.Y.Z upstream/master
```

7. Upload the packages to the PyPI instance:

```
twine upload --sign dist/*
```

8. Check the [PyPI package page](#).
9. Make sure the package can be installed:

```
mkvirtualenv skbuild-pip-install  
pip install scikit-build  
rmvirtualenv skbuild-pip-install
```

10. Add a `Next Release` section back in *CHANGES.rst* and merge the result.
11. Push local changes
