**TripalTestSuite** is a composer package that handles common test practices such as bootstrapping Drupal before running the tests, creating test file, and creating and managing database seeders (files that seed the database with data for use in testing).

# CHAPTER 1

---

Support

---

Please visit our issues queue on [Github](#) for any questions, issues or contributions.

TripalTestSuite is licensed under GPLv3.

## 2.1 Installation

### 2.1.1 Adding Test Suite to a New Project

Within your Drupal module path (e.g. `sites/all/modules/my_module`), run the following.

```
composer require statonlab/tripal-test-suite --dev
```

### 2.1.2 Automatic Set Up

TestSuite can automatically configure your tests directory, PHPUnit bootstrap files, and travis continuous integration file as well as provide an example test and an example database seeder to get you started.

From your module's directory, execute:

```
# You may specify the module name or leave it blank.  
# When left blank, the name of the current directory will be used as the module name.  
./vendor/bin/tripaltest init [MODULE_NAME]
```

This will:

- Set up the testing framework by creating the tests directory, `phpunit.xml` and `tests/bootstrap.php`
- Create an example test in `tests/ExampleTest.php`
- Create a `DatabaseSeeders` folder and an example seeder in `tests/DatabaseSeeders/UsersTableSeeder.php`
- Create `DevSeedSeeder.php` in `DatabaseSeeders`. See the *Database Seeders* section to learn more about automatically populating the database with biological data.

- Create an example `.env` file.
- Create `.travis.yml` configured to use a tripal3 docker container to run your tests

You can now write tests in your `tests` folder. To enable continuous integration testing, push your module to github and enable Travis CI.

### 2.1.3 Environment Variables

When the `init` command is run (see: *Automatic Set Up*), an example `.env` file is created in `tests/`. This file should be copied to `tests/.env` and modified to describe **your specific Drupal environment**.

```
# tests/.env
BASE_URL=http://localhost
DRUPAL_ROOT=/var/www/html
FAKER_LOCALE=en_US
```

- `BASE_URL`: The URL of your site. This is where you point your browser to view your site.
- `DRUPAL_ROOT`: The absolute path to your Drupal site. On Unix machines, this is often `/var/www/html`, but it may be different on your setup.
- `FAKER_LOCALE`: Test Suite uses the [Faker package](#) to create fake data in factories. You can change the locale setting for the fake words used.

If the `Drupal_ROOT` variable is not set correctly, Drupal may not be bootstrapped correctly, and your tests may fail.

### 2.1.4 Forcing initialization

To force replacing files that tripaltest have perviously generated, you can use the `--force` flag. You will need to confirm this flag by typing `y` and hitting `enter`.

```
./vendor/bin/tripaltest init --force
```

### 2.1.5 Joining an Existing Project

If Test Suite is already configured for a project (for example, if you clone Tripal and want to run tests), the `composer.json` file already specifies what version of Test Suite is in use. To install it, execute the below command.

```
composer install
```

**Warning:** Before you can run tests, you'll first need to configure your *Environment Variables* in the `.env` file.

## 2.2 Testing

### 2.2.1 Creating Tests

Using `tripaltest`, you can create test files pre-populated with all the requirements. To create a new test, run the following command from your module's root directory:

```
# Creates a test file called ExampleTest.php in the tests folder
./vendor/bin/tripaltest make:test ExampleTest

# Creates a test file called ExampleTest.php in tests/Features/Entities
# This will automatically detect and configure the namespace of your script
./vendor/bin/tripaltest make:test Features/Entities/ExampleTest
```

**Warning:** You should not include `tests/` in your path, nor should you specify a file extension.

**Warning:** Test names should end with `Test` for phpunit to recognize them.

## 2.2.2 Running Tests

Tripal Test Suite auto installs PHPunit as part of it's dependencies in `composer.json`. Therefore, running tests in Tripal Test Suite is done via `phpunit` as such:

```
./vendor/bin/phpunit
```

The command above, will read your `phpunit.xml` and runs the tests accordingly.

## 2.2.3 TripalTestCase

Test classes should extend the `TripalTestCase` class. Once extended, bootstrapping Drupal and reading your `.env` file is done automatically when the first test is run.

```
namespace Tests;

use StatonLab\TripalTestSuite\TripalTestCase;

class MyTest extends TripalTestCase {
}
```

**Attention:** If you define a `setUp` method within a test class, be sure to call `parent::setUp!`

## 2.2.4 Testing HTTP Requests

`TripalTestSuite` provides a comprehensive HTTP testing methods. It allows you to call site urls and check that your Drupal menu items are working as expected.

For example, the following tests that the homepage is accessible and that the name of the website is present in the response.

```
public function testHomePage() {
    // Send a GET request
    $response = $this->get('/')

    // Verify the HTTP response code is "200 OK" and that the site name is visible
```

(continues on next page)

(continued from previous page)

```
$response->assertStatus(200)
    ->assertSee('My Site');
}
```

### **Available HTTP Testing Methods**

The following table describes all available HTTP methods in any test class that extends TripalTestSuite:

name	parameters	Description	Return
<ul style="list-style-type: none"> <li>• <code>\$this-&gt;get()</code></li> </ul>	<ul style="list-style-type: none"> <li>• <b>\$url</b> string The url to call</li> <li>• <b>\$params</b> array Query parameters.</li> <li>• <b>\$headers</b> array Additional HTTP headers</li> </ul>	Sends a GET request	TestResponse
<code>\$this-&gt;post()</code>	<ul style="list-style-type: none"> <li>• <b>\$url</b> string The url to call</li> <li>• <b>\$params</b> array Form request parameters.</li> <li>• <b>\$headers</b> array Additional HTTP headers</li> </ul>	Sends a POST request	TestResponse
<code>\$this-&gt;put()</code>	<ul style="list-style-type: none"> <li>• <b>\$url</b> string The url to call</li> <li>• <b>\$params</b> array Query parameters.</li> <li>• <b>\$headers</b> array Additional HTTP headers</li> </ul>	Sends a PUT request	TestResponse
<code>\$this-&gt;patch()</code>	<ul style="list-style-type: none"> <li>• <b>\$url</b> string The url to call</li> <li>• <b>\$params</b> array Query parameters.</li> <li>• <b>\$headers</b> array Additional HTTP headers</li> </ul>	Sends a PATCH request	TestResponse
<code>\$this-&gt;delete()</code>	<ul style="list-style-type: none"> <li>• <b>\$url</b> string The url to call</li> <li>• <b>\$params</b> array Query parameters.</li> <li>• <b>\$headers</b> array Additional HTTP headers</li> </ul>	Sends a DELETE request	TestResponse

The TestResponse returned from the HTTP requests, provide the following set of assertion methods:

name	Parameters	Description
<code>\$response-&gt;assertStatus(\$code)</code>	<code>\$code int</code>	Verify the returned HTTP status code is equal to <code>\$code</code>
<code>\$response-&gt;assertSee(\$content)</code>	<code>\$content string</code>	Verify the given string is present in the returned response body (i.e. HTML, JSON, etc)
<code>\$response-&gt;assertJson(\$structure)</code>	<code>\$structure array</code>	Verifies that the returned JSON matches the given structure (see below for example)
<code>\$response-&gt;assertSuccessful()</code>	<code>\$code int</code>	Verify the returned HTTP status code is between 200 and 299, which are HTTP's successful response codes

### 2.2.5 User Authentication

Authenticating a user with TripalTestSuite is very simple using the `actingAs` method. When authenticating a user with TripalTestSuite, the user is automatically signed out by the end of each test method, which guarantees that your other tests are using the anonymous user unless you specifically tell it otherwise.

```
public function testExample() {
    // Authenticate the superuser who has an id 1
    $this->actingAs(1);

    // Verify that the user is the admin user
    global $user;
    $this->assertTrue(1 === $user->uid);
}
```

**Attention:** The `actingAs` method can take a user id to authenticate or a Drupal user object.

## 2.3 Database Operations

### 2.3.1 Database Seeders

Database seeders are also supported in TripalTestSuite. They give you the ability to create reusable seeders that can be run using the `tripaltest` command line tool.

#### Example Seeders

Several example database seeders are provided in `tests/DatabaseSeeders/examples`. These will not run unless they are copied to `tests/DatabaseSeeders/`.

#### Creating Database Seeders

DB seeders can also be created automatically using `tripaltest`:

```
./vendor/bin/tripaltest make:seeder ExampleTableSeeder
```

The above command will create `ExampleTableSeeder.php` in `tests/DatabaseSeeders/` pre-populated with the necessary namespace, methods and properties.

## Using Database Seeders

DB seeders support an important method: `up()`. The `up()` method is used to insert data into the database when the test class is initialized, making it available to all tests within the class. The following is an example of a Seeder class.

```
<?php

namespace Tests\DatabaseSeeders;

use StatonLab\TripalTestSuite\Database\Seeder;

class UsersTableSeeder extends Seeder
{
    /**
     * Seeds the database with users.
     */
    public function up()
    {
        $new_user = [
            'name' => 'test user',
            'pass' => 'secret',
            'mail' => 'test@example.com',
            'status' => 1,
            'init' => 'Email',
            'roles' => [
                DRUPAL_AUTHENTICATED_RID => 'authenticated user',
            ],
        ];

        // The first parameter is sent blank so a new user is created.
        user_save(new stdClass(), $new_user);
    }
}
```

## Running Seeders

You can also run the seeder manually by using the static `seed()` method. For example, within a test class, you can run `$seeder = UsersTableSeeder::seed()` which runs the `up()` method and returns an initialized seeder object. If you are using the `DBTransaction` trait, the data will be automatically rolled at the end of each test function.

**Attention:** Don't forget to import your seeder at the top of the test file: `use Tests\DatabaseSeeders\UsersTableSeeder;`

The other option is to run it using `tripaltest` as follows

```
# run all available seeders
tripaltest db:seed

# Run a specific seeder by providing the class name
tripaltest db:seed ExampleSeeder
```

**Attention:** Running the seeder manually in a test function with `DBTransaction` enabled, means that the data is available only to that function and nothing else. However, running it using `tripaltest` makes it always available unless explicitly deleted.

### Retrieving Seeder Data

If your seeder returns any data, you can obtain the returned record by manually running the seeder in your test. See below for an example:

```
<?php
// Seeder Class
class MySeeder extends Seeder {
    public function up() {
        // Generate some data.
        $data = db_query(...);

        return $data;
    }
}

// Test Class
class MyTest extends TripalTestCase {
    public function testExample() {
        $seeder = new MySeeder();
        $data = $seeder->up();

        // Run some tests using the generated data
        // ...
    }
}
```

### Using DevSeed for Quick Biological Data Seeding

Tripal Test Suite ships with a default seeder called `DevSeedSeeder`. It is located at `tests/DatabaseSeeders/examples/`: to use it, copy it to `tests/DatabaseSeeders/`. This seeder provides a quick and automated way of seeding your database with biological data such as organisms, mRNAs, BLAST annotations and InterProScan annotations. The data in the default seeder is obtained from [Tripal DevSeed](#), which is a developer mini-set of biological data.

**Attention:** The `DevSeed` seeder must be copied from `tests/DatabaseSeeders/examples/` to `tests/DatabaseSeeders/`. Seeders in the examples folder will not run.

`DevSeed` uses factories and is therefore **only appropriate for testing and development** and should not be run on a production site.

**Attention:** `DevSeedSeeder.php` becomes available after running `tripaltest init`. The `init` command will not override existing files unless you specify the `--force` flag so it's safe to run it to get only the `DevSeeder`.

By default, the `DevSeed` comes with all sub-loaders enabled. To configure the `DevSeed` seeder, comment out data types you don't need in the public static variables section. Then, you can run the seeder using `tripaltest db:seed`

DevSeedSeeder.

1. If you haven't already, copy the seeder from `tests/DatabaseSeeders/examples` to `tests/DatabaseSeeders/`.
2. Open `DatabaseSeeders/DevSeedSeeder.php`
3. You'll notice a few commented properties in the top of the file.
4. Uncomment and modify the properties to your need.
5. Carefully follow the instructions in this section. All loaders require an organism as well, but some are dependent on previous loaders.
6. Next, run `tripaltest db:seed DevSeedSeeder`
7. If the seeder runs successfully, you'll be able to see all the records in your Chado database.

The records provided by DevSeed are not published to your site as entities. You can do that by adding `$this->publish('CHADO_TABLE')` at the end of the `up()` method of the `DevSeedSeeder`. Replace `CHADO_TABLE` with the name of the table such as `feature` for mRNAs and `analysis` for analyses. Or, if you prefer, you can use the Tripal admin interface to publish the records.

## 2.3.2 Factories

DB factories provide a method to populate the database with fake data. Using factories, you won't have to run SQL queries to populate the Database in every test. Since they are reusable, you can define one factory for each table and use them across all tests. Usage example:

```
# Generates 100 controlled vocabularies.
# @return an array of vocabularies
$controlledVocabs = factory('chado.cv', 100)->create()
```

Factories should **only be used for testing and development purposes**.

### Defining Factories

Factories live in `tests/DataFactory.php`. If you don't have that file, create it. Note that this file is auto created with `tripaltest init`.

Example `DataFactory` file:

```
<?php
use StatonLab\TripalTestSuite\Database\Factory;

Factory::define('chado.cv', function (Faker\Generator $faker) {
    return [
        'name' => $faker->name,
        'definition' => $faker->text,
    ];
});
```

As shown in the example above, using `Factory::define()`, we can define new factories. The `define` method takes the following parameters:

Parameter	Type	Description	Example
\$table	string	The table name preceded with the schema name if the schema is not public	chado. cv or node
\$callback	callable	The function that generates the array. A Faker\Generator instance is automatically passed to the callable	see above for exam- ple
\$primary_key	string	<b>OPTIONAL</b> The primary key for the given table. Primary keys auto discovered for CHADO tables only. If the factory wasn't able to find the primary key, an Exception will be thrown	nid or cv_id

### Checking if a Factory Exists

To determine whether a factory exists, you can use the `Factory::exists($table)` method:

```
<?php
// Import the Factory class
use StatonLab\TripalTestSuite\Database\Factory;

Factory::exists('user'); // true

// For chado tables always precede with `chado.`
Factory::exists('chado.feature'); // true
```

### Using Factories

Once defined, factories can be used in test files directly or in database seeders. Usage:

```
# Create a single CV record
$cv = factory('chado.cv')->create();
echo "$cv->name\n";

# Create 100 CV records
$cvs = factory('chado.cv', 100)->create();

foreach ($cvs as $cv) {
    echo "$cv->name\n";
}
```

### Overriding Defaults

Sometimes you need to override a column to be a static predictable value. The `create()` method accepts an array of values to override the faker data with. Example:

```
# Let's make sure the cvterm has a specific cv id
$cv = factory('chado.cv')->create();
$cv_term = factory('chado.cvterm', 100)->create([
    'cv_id' => $cv->cv_id,
])
```

The above example creates 100 cv terms that have the same cv\_id.

Factories should **only be used for testing and development purposes**. This is because they are **recursive** and create the records linked via foreign key. They do this **even if you override the default** for the linked record.

### 2.3.3 Using DB Transactions to Automatically Rollback Database Changes

Using DB transactions cleans up the database after every test by rolling back the database to the original state before the test started. Therefore, anything added to the database in one test function will not be available for the next function. If you'd like data to be available for all of the tests, see [database seeders](#) above.

To activate DB Transactions, simply add the DBTransaction trait to your test class:

```
namespace Tests;

use StatonLab\TripalTestSuite\TripalTestCase;
use StatonLab\TripalTestSuite\DBTransaction;

class MyTest extends TripalTestCase {
    use DBTransaction;
}
```

The trait will automatically activate DB transactions and rollback the database when the test is finished.

**Warning:** If the code you are testing requires a transaction, Postgres will fail since it does not support nested transactions.

### 2.3.4 Publishing Tripal Entities

We provide an easy way to convert your chado records into entities. This is the equivalent of publishing Tripal content using the GUI.

Publishing records is possible in both database seeders and directly in the test class.

The following publishes all features in `chado.feature` if they have not been published yet.

```
// Get the cvterm id of mRNA
$cvterm = chado_select_record('cvterm', ['cvterm_id'], ['name' => 'mRNA'])[0];

// Create 100 mRNA records
$features = factory('feature', 100)->create(['type_id' => $cvterm->cvterm_id]);

// Publish all features in chado.feature
$this->publish('feature');
```

The following publishes only the given feature ids:

```
// Get the cvterm id of mRNA
$cvterm = chado_select_record('cvterm', ['cvterm_id'], ['name' => 'mRNA'])[0];

// Create 100 mRNA records
$features = factory('feature', 100)->create(['type_id' => $cvterm->cvterm_id]);

// Get the ids of our new features
$feature_ids = [];
```

(continues on next page)

(continued from previous page)

```
foreach ($features as $feature) {
    $feature_ids[] = $feature->feature_id;
}

// Publish only the given features
$this->publish('feature', $feature_ids);
```

The previous examples create mRNA entities.

**Attention:** An mRNA bundle must already be available before running this script.

## 2.4 Helper Methods

TripalTestSuite provides a set of helper methods to automate tedious aspects of testing.

### 2.4.1 Silently Testing Printed Output

Since tests should run “silently”, i.e. without printing output to the screen, we’d have to create an output buffer to collect printed strings into a variable. In PHP, this can be done as such:

```
// Suppress tripal errors
putenv("TRIPAL_SUPPRESS_ERRORS=TRUE");
ob_start();

// Run the call
echo "testing";
$output = ob_get_contents();

// Clean the buffer and unset tripal errors suppression
ob_end_clean();
putenv("TRIPAL_SUPPRESS_ERRORS");
```

However, TripalTestSuite provides a `silent()` method that automates this process, provides helpful assertions and supports larger strings. Example usage:

```
$output = silent(function() {
    echo "testing";
});
$output->assertSee('testing'); // true!
```

**Warning:** This method has a maximum string size to avoid memory leaks. The size is set in PHP’s ini file as `output_buffering`, which by default is set to 4KB. If you would like to collect larger strings, you must adjust your PHP settings.

### 2.4.2 Assertions and Methods

The `silent` method returns a `SilentResponse` which provides the following methods.

Method	Arguments	Description
assertSee()	\$value mixed	Asserts that the given value is present in the suppressed printed output
assertReturnEquals()	\$value mixed	Asserts that the given value equals the returned value from the called function
assertJsonStructure()	\$structure array “\$data“ array <b>Optional</b>	Asserts that the given structure matches that of the suppressed printed output
getContent()	None	Get the suppressed printed content as a string
getReturnValue()	None	Get the returned value from the called function

### Examples

```
$output = silent(function() {
    drupal_json_output(['key' => 'value']);
    return true;
});

$output->assertSee('value')
    ->assertJsonStructure(['key'])
    ->assertReturnEquals(true);
```

You can also call methods directly in the Callable function:

```
// Assume we have the following function
function tripal_print_message($message) {
    echo $message;
}

$output = silent(function() {
    tripal_print_message('tripal test suite');
});
$output->assertSee('test');

// Get the output as a string
$rawOutput = $output->getContent();
```

### 2.4.3 Access Private and Protected Properties and Methods of Objects

TripalTestSuite provides a reflect() method that accepts an object and makes all of the properties and methods public and available for testing. Assume we have the following class:

```
class PrivateClass
{
    private $private;

    public function __construct($private = 'private')
```

(continues on next page)

(continued from previous page)

```
{
    $this->private = $private;
}

protected function myProtected()
{
    return 'protected';
}

private function privateWithArgs($one, $two)
{
    return $one.' '.$two;
}
}
```

Because of the functions and properties of the class are private or protected, we normally would not be able to access any of them. However, we can force access using the reflect helper. See below for an examples.

## 2.4.4 Accessing Private and Protected Methods

```
// Pass an initialized class to the reflect method
$myObject = new PrivateClass();
$privateClass = reflect($myObject);

// Accessing protected methods
$value = $privateClass->myProtected();
$this->assertEquals('protected', $value);

// Accessing private methods with arguments
$value = $privateClass->privateWithArgs('one', 'two');
$this->assertEquals('one two', $value);
```

## 2.4.5 Accessing Properties

```
// Pass an initialized class to the reflect method
$myObject = new PrivateClass();
$privateClass = reflect($myObject);

$this->assertEquals('private', $privateClass->private);
```

## 2.5 Upgrading TripalTestSuite

Since we are using composer to manage releases, running `composer update` should update all your dependencies to the latest version. However, you need to be aware of how `composer` deals with [versioning](#).

Upgrading to a major versions (e.g, from 1.5.0 to 2.0.0), will require that you change the specified version in your `composer.json` file. Upgrading minor version (e.g, 1.0.0 to 1.1.0) can be made automatic by specifying `1.*` as your `tripal-test-suite` version.

## 2.6 Training Videos

### 2.6.1 Creating and Running Basic Tests with Tripl Test Suite

```

- Installing phpspec/phpspec (1.9.0): Loading from cache

## 2.6.3 Seeding and Publishing Data with Tripal Test Suite

## 2.7 Tips and Tricks for Writing Good Tests

### 2.7.1 Generating Fake Variables: Faker

**Note:** Are you creating fake values to insert into Chado? If so, check out **Factories** which will generate all the fake values automatically. For example:

```

# Generates 100 controlled vocabularies.
# @return an array of vocabularies
$controlledVocabs = factory('chado.cv', 100)->create()

```

The recommended method to create fake values for use in testing is to use the PHP Faker library by @fzaninotto: <https://github.com/fzaninotto/Faker>. To use this library in your Tripal tests, simply include it at the top of the class:

```

use StatonLab\TripalTestSuite\DBTransaction;
use StatonLab\TripalTestSuite\TripalTestCase;
use Faker\Factory;

```

(continues on next page)

(continued from previous page)

```
class ExampleTest extends TripalTestCase {
  /**
   * Stuff
   */
}
```

Then instantiate it in your test method and create fake data using one of the various methods available through the library.

```
private function create_version() {

  // Generate a fake version.
  $faker = Factory::create();
  $version = $faker->randomFloat(2, 1, 5);
  return $version;
}
```

More more information on what is provided by the fake library, check out their documentation here: [github.com/fzaninotto/Faker](https://github.com/fzaninotto/Faker)

## 2.7.2 Test Guidelines

See also: [The Tripal test guidelines](#). Tests you write that are included in the core Tripal repository should follow these standards.

## 2.8 Contribution Guidelines

Thank you for your interest in contributing to Tripal Test Suite! This guide should help you get setup quickly to start contributing.

### 2.8.1 Creating a Development Environment

It is highly recommended to use Docker to create your development environment. This would guarantee that we share identical environments and help reduce debugging efforts.

To get started:

- Fork this repository (see [guide on GitHub](#))
- Clone your fork `git clone https://github.com/USERNAME/TripalTestSuite.git` (where USERNAME is your Github username).
- Navigate to TripalTestSuite `cd TripalTestSuite`
- Install dependencies `composer install`
- Boot up Docker `docker-compose up -d`
- Finally, checkout a new branch and make your changes `git checkout -b my-branch-name` (please make the branch name descriptive)

**Attention:** If introducing new features, please provide unit tests for the new features.

## 2.8.2 Performing Tests

We require that all new features and contributions are fully unit-tested. There are two types of tests:

- TripalTestSuite features that do not require Drupal (such as the `reflect` and `silent` helper methods)
- Features that depend on Drupal (such as factories)

If your feature doesn't require Drupal, the tests should go to `tests/Feature`. If it does require to be part of a module, you can use the `test_module` in `tests/test_module`. Within the module, there will be a `tests` folder where you can test your contributions.

## 2.8.3 Structure

All code for this package should go in the `src/` directory. In there, you'll find:

- **Concerns:** Add-on features that must be **PHP traits**. Traits are ideal when a feature makes use of the main class functionality or can be chained. For example, the `InteractsWithAuthSystem` offers `actingAs()` method that can be chained with HTTP requests as such: `$this->actingAs(1)->get('/myform');`
- **Console:** Any commands that `tripaltest` offers go here. Note that all commands must be registered in `kernel.php`.
- **Database:** Any database related features such as support for factories, publishing entities and seeding.
- **Exceptions:** Any custom Exceptions.
- **Helpers:** Functions that perform simple operations or make classes easier to access. For example, `factory()` is a helper method.
- **Mocks:** Objects that simulate the behavior of other (real) objects. [Read more about mocks](#)
- **Services:** Isolated classes that offer special functionality. Most classes that should be used within a test, such as `SilentResponse`, should also offer a helper method. For example, the `Factory` class offers the `factory()` helper.

## 2.8.4 Including PHP Files

Tripal Test Suite uses PSR-4 loading standards and therefore there is no need for you to manually include any file.

**Warning:** Namespaces matter in class/trait loading. The namespace must contain all sub directories. For example, the `Concerns/PublishesData.php` file must have the namespace `StatonLab\TripalTestSuite\Concerns;`. All namespaces should be preceded with `StatonLab\TripalTestSuite`.

## 2.8.5 Code Style

We conform to [PSR-2](#) code style
