[ACME](#) is Automatic Certificate Management Environment, a protocol that allows clients and certificate authorities to automate verification and certificate issuance. The ACME protocol is used by the free [Let's Encrypt](#) Certificate Authority.

`txacme` is an implementation of the protocol for [Twisted](#), the event-driven networking engine for Python.

`txacme` is still under heavy development, and currently only an implementation of the client side of the protocol is planned; if you are interested in implementing or have need of the server side, please get in touch!

`txacme`'s documentation lives at [Read the Docs](#), the code on [GitHub](#). It's rigorously tested on Python 2.7, 3.4+, and PyPy.

## 1.1 Using txacme

There are several possible ways to make use of txacme:

- An issuing service for keeping certificates in a certificate store up to date;
- A server endpoint, which may be used anywhere an endpoint is accepted, that combines the issuing service with TLS SNI for certificate mapping;
- A server endpoint string parser, which can be used anywhere a server endpoint string es accepted, that produces a server endpoint.

While the server endpoint string parser is a convenient high-level API the lower-level APIs (the issuing service and server endpoint) may be useful for better integration with existing systems. For example, if the requirements for storing certificates were more complex than a directory on a filesystem, one might implement a certificate store that communicated with a REST webservice or directly with a database and pass an instance of this to the server endpoint.

### 1.1.1 Server endpoint string

The simplest way to use txacme is the stream server endpoint string. Two endpoint parsers are provided, under the `le:` (Let's Encrypt) and `lets:` (Let's Encrypt Test in Staging) prefixes. The endpoint takes as parameters a directory to store certificates in, and the underlying endpoint to listen on. One might use the following command to start a Twisted web server on TCP port 443 and store certificates in the `/srv/www/certs` directory:

```
$ twistd -n web --port lets:/srv/www/certs:tcp:443 --path /srv/www/root
```

---

**Note:** The certificate directory must already exist, and be writable by the user the application is running as.

---

**Note:** The Let's Encrypt staging environment generates certificates signed by *Fake LE Intermediate X1*, but does not have the [stringent limits](#) that the production environment has, so using it for testing before switching to the production environment is highly recommended.

---

The ACME client key will be stored in `client.key` in the certificate directory, if this file does not exist a new key will automatically be generated.

Certificates (and chain certificates and keys) in PEM format will be stored in the certificate directory using filenames based on the servername that the client sends by SNI, e.g. `some.domain.name.pem`. The contents of the directory are documented in more detail [here](#). If there is no existing certificate available for a domain, an empty file should be

created to have one issued on startup; the behaviour is as if the certificate had expired. Importantly, clients that do not perform SNI will not be able to connect to the endpoint.

At startup, and every 24 hours, a check will be performed for expiring certificates; if a certificate will expire in less than 30 days' time, it will be reissued. If the reissue fails, it will be retried at the next check. If a certificate will expire in less than 15 days' time, and reissue fails, a message will be logged at *CRITICAL* level.

---

**Note:** This endpoint uses the `tls-sni-01` challenge type to perform authorization; this requires that the endpoint is reachable on port 443 for those domains (possibly via port forwarding).

---

## Sharing certificates

A certificate directory can be shared amongst multiple applications by using `le`: for the application running on port 443 to keep the certificates up to date, and `txsni`: for other applications to make use of certificates in the same directory.

### 1.1.2 Server endpoint

The endpoint can be instantiated directly as well; this allows extra customizations beyond what the string syntax provides for. Most of the parameters that can be passed correspond to the parameters of the *issuing service*.

```
class txacme.endpoint.AutoTLSEndpoint (reactor,          directory,          client_creator,
                                       cert_store,       cert_mapping,       sub_endpoint,
                                       check_interval=datetime.timedelta(1),
                                       reissue_interval=datetime.timedelta(30),
                                       panic_interval=datetime.timedelta(15), panic=<function
                                       _default_panic>, generate_key=<functools.partial
                                       object>)
```

A server endpoint that does TLS SNI, with certificates automatically (re)issued from an ACME certificate authority.

#### Parameters

- **reactor** – The Twisted reactor.
- **directory** – `twisted.python.url.URL` for the ACME directory to use for issuing certs.
- **client\_creator** (Callable[[reactor, twisted.python.url.URL], Deferred[*txacme.client.Client*]]) – A callable called with the reactor and directory URL for creating the ACME client. For example, `partial(Client.from_url, key=acme_key, alg=RS256)`.
- **cert\_store** (*ICertificateStore*) – The certificate store containing the certificates to manage. For example, *txacme.store.DirectoryStore*.
- **cert\_mapping** (*dict*) – The certificate mapping to use for SNI; for example, `txsni.sniimap.HostDirectoryMap`. Usually this should correspond to the same underlying storage as `cert_store`.
- **check\_interval** (*timedelta*) – How often to check for expiring certificates.
- **reissue\_interval** (*timedelta*) – If a certificate is expiring in less time than this interval, it will be reissued.
- **panic\_interval** (*timedelta*) – If a certificate is expiring in less time than this interval, and reissuing fails, the panic callback will be invoked.

- **panic** (Callable[[Failure, str], Deferred]) – A callable invoked with the failure and server name when reissuing fails for a certificate expiring in the `panic_interval`. For example, you could generate a monitoring alert. The default callback logs a message at *CRITICAL* level.
- **generate\_key** – A 0-arg callable used to generate a private key for a new cert. Normally you would not pass this unless you have specialized key generation requirements.

**listen** (*protocolFactory*)

Start an issuing service, and wait until initial issuing is complete.

### 1.1.3 Issuing service

The *server endpoint* is a simple wrapper that combines the functionality of the `txsni` endpoint for handling SNI, and the issuing service which takes care of (re)issuing certificates using an ACME service.

```
class txacme.service.AcmeIssuingService(cert_store, client_creator, clock, responders,
                                       email=None, check_interval=datetime.timedelta(1),
                                       reissue_interval=datetime.timedelta(30),
                                       panic_interval=datetime.timedelta(15),
                                       panic=<function _default_panic>, generate_key=<functools.partial object>)
```

A service for keeping certificates up to date by using an ACME server.

#### Parameters

- **cert\_store** (*ICertificateStore*) – The certificate store containing the certificates to manage.
- **client\_creator** (Callable[[], Deferred[*txacme.client.Client*]]) – A callable called with no arguments for creating the ACME client. For example, `partial(Client.from_url, reactor=reactor, url=LETSENCRYPT_STAGING_DIRECTORY, key=acme_key, alg=RS256)`.
- **clock** – *IReactorTime* provider; usually the reactor, when not testing.
- **responders** (List[*IResponder*]) – Challenge responders. Usually only one responder is needed; if more than one responder for the same type is provided, only the first will be used.
- **email** (*str*) – An (optional) email address to use during registration.
- **check\_interval** (*timedelta*) – How often to check for expiring certificates.
- **reissue\_interval** (*timedelta*) – If a certificate is expiring in less time than this interval, it will be reissued.
- **panic\_interval** (*timedelta*) – If a certificate is expiring in less time than this interval, and reissuing fails, the panic callback will be invoked.
- **panic** (Callable[[Failure, str], Deferred]) – A callable invoked with the failure and server name when reissuing fails for a certificate expiring in the `panic_interval`. For example, you could generate a monitoring alert. The default callback logs a message at *CRITICAL* level.
- **generate\_key** – A 0-arg callable used to generate a private key for a new cert. Normally you would not pass this unless you have specialized key generation requirements.

**issue\_cert** (*server\_name*)

Issue a new cert for a particular name.

If an existing cert exists, it will be replaced with the new cert. If issuing is already in progress for the given name, a second issuing process will *not* be started.

**Parameters** `server_name` (*str*) – The name to issue a cert for.

**Return type** `Deferred`

**Returns** A deferred that fires when issuing is complete.

**when\_certs\_valid()**

Get a notification once the startup check has completed.

When the service starts, an initial check is made immediately; the deferred returned by this function will only fire once reissue has been attempted for any certificates within the panic interval.

---

**Note:** The reissue for any of these certificates may not have been successful; the panic callback will be invoked for any certificates in the panic interval that failed reissue.

---

**Return type** `Deferred`

**Returns** A deferred that fires once the initial check has resolved.

The *ICertificateStore* and *IResponder* interfaces are the main extension points for using the issuing service directly. For example, a custom implementation of *ICertificateStore* might manage the certificate configuration of a cloud load balancer, implementing the `dns-01` challenge type by modifying DNS entries in the cloud DNS configuration.

## 1.2 Certificates directory

The layout of the certificates directory used by `DirectoryStore` (and thus the `le:` and `lets:` endpoints) is coordinated with `txsni` to allow sharing a certificates directory with other applications. The `txsni` and `txacme` maintainers have committed to coordination of any future changes to the contents of this directory to ensure continued compatibility.

At present, the following entries may exist in this directory:

- `<server name>.pem`

A file containing a certificate and matching private key valid for `<server name>`, serialized in PEM format.

- `client.key`

A file containing an ACME client key, serialized in PEM format.

All other filenames are currently reserved for future use; introducing non-specified files or directories into a certificates directory may result in conflicts with items specified by future versions of `txacme` and/or `txsni`.

## 1.3 API stability

`txacme` is versioned according to [SemVer 2.0.0](#). In addition, since `SemVer` does not make this explicit, versions following `txacme 1.0.0` will have a “rolling compatibility” guarantee: new major versions will not break behaviour that did not already emit a deprecation warning in the latest minor version of the previous major version series.

The current version number of `0.9.x` is intended to reflect the not-quite-finalized nature of the API. While it is not expected that the API will change drastically, the `0.9` version series is intended to allow space for users to experiment

and identify any issues obstructing their use cases so that these can be corrected before the API is finalized in the 1.0.0 release.

## 1.4 txacme changelog

### 1.4.1 Txacme 0.9.1 (2016-12-08)

#### Features

- **INCOMPATIBLE CHANGE:** `AcmeIssuingService` now takes a client creator, rather than a client, and invokes it for every issuing attempt. (#21)
- **INCOMPATIBLE CHANGE:** The `*_DIRECTORY` constants are now in `txacme.urls`. (#28)
- **INCOMPATIBLE CHANGE:** `IResponder.start_responding` and `IResponder.stop_responding` now take the `server_name` and `challenge` object in addition to the challenge response object. (#60)
- `AcmeIssuingService` now logs info messages about what it is doing. (#38)
- `txacme.challenges.LibcloudDNSResponder` implements a dns-01 challenge responder using libcloud. Installing `txacme[libcloud]` is necessary to pull in the dependencies for this. (#59)
- `txacme.challenges.HTTP01Responder`, an http-01 challenge responder that can be embedded into an existing `twisted.web` application. (#65)
- `txacme.endpoint.load_or_create_client_key` gets a client key from the certs directory, using the same logic as the endpoints. (#71)
- `AcmeIssuingService` now accepts an `email` parameter which it adds to the ACME registration. In addition, existing registrations are updated with this email address. (#72)
- `AcmeIssuingService` now has a `public_issue_cert` method for safely issuing a new cert on demand. (#76)

#### Bugfixes

- `txacme.client.JWSClient` now automatically retries a POST request that fails with a `badNonce` error. (#66)
- `txacme.store.DirectoryStore` now handles bytes mode paths correctly. (#68)
- The txacme endpoint plugin now lazily imports the rest of the code, avoiding `ReactorAlreadyInstalled` errors in various cases. (#79)

#### Improved Documentation

- The contents of the certificates directory, and compatibility with `txsni`, is now documented. (#35)

#### Misc

- #67

## 1.4.2 Txacme 0.9.0 (2016-04-10)

### Features

- Initial release! (#23)

## 1.5 txacme

### 1.5.1 txacme package

#### Subpackages

##### txacme.challenges package

#### Module contents

**class** txacme.challenges.HTTP01Responder

An http-01 challenge responder for txsni.

**start\_responding** (*server\_name, challenge, response*)

Add the child resource.

**stop\_responding** (*server\_name, challenge, response*)

Remove the child resource.

**class** txacme.challenges.LibcloudDNSResponder (*reactor, thread\_pool, driver, zone\_name, settle\_delay*)

A dns-01 challenge responder using libcloud.

**Warning:** Some libcloud backends are broken with regard to TXT records at the time of writing; the Route 53 backend, for example. This makes them unusable with this responder.

---

**Note:** This implementation relies on invoking libcloud in a thread, so may not be entirely production quality.

---

**classmethod** **create** (*reactor, driver\_name, username, password, zone\_name=None, settle\_delay=60.0*)

Create a responder.

#### Parameters

- **reactor** – The Twisted reactor to use for threading support.
- **driver\_name** (*str*) – The name of the libcloud DNS driver to use.
- **username** (*str*) – The username to authenticate with (the meaning of this is driver-specific).
- **password** (*str*) – The password to authenticate with (the meaning of this is driver-specific).
- **zone\_name** (*str*) – The zone name to respond in, or `None` to automatically detect zones. Usually auto-detection should be fine, unless restricting responses to a single specific zone is desired.
- **settle\_delay** (*float*) – The time, in seconds, to allow for the DNS provider to propagate record changes.

**start\_responding** (*server\_name*, *challenge*, *response*)  
Install a TXT challenge response record.

**stop\_responding** (*server\_name*, *challenge*, *response*)  
Remove a TXT challenge response record.

**class** txacme.challenges.**TLSSNI01Responder**

A `tls-sni-01` challenge responder for txsni.

**start\_responding** (*server\_name*, *challenge*, *response*)  
Put a context into the mapping.

**stop\_responding** (*server\_name*, *challenge*, *response*)  
Remove a context from the mapping.

**wrap\_host\_map** (*host\_map*)  
Wrap a txsni host mapping.

The wrapper should be passed to `txsni.snimap.SNIMap`; any active challenge server names will override entries in the wrapped map, but this scenario is unlikely to occur due to the invalid nature of these names.

## txacme.test package

### Submodules

**txacme.test.doubles module** Test doubles.

**class** txacme.test.doubles.**SynchronousReactorThreads**  
Bases: `object`

An implementation of `IReactorFromThreads` that calls things synchronously in the same thread.

### txacme.test.matchers module

**class** txacme.test.matchers.**ValidForName** (*name*)

Matches when the matchee object (must be a `Certificate` or `CertificateSigningRequest`) is valid for the given name.

**txacme.test.strategies module** Miscellaneous strategies for Hypothesis testing.

txacme.test.strategies.**dns\_labels** ()  
Strategy for generating limited charset DNS labels.

txacme.test.strategies.**dns\_names** ()  
Strategy for generating limited charset DNS names.

txacme.test.strategies.**urls** ()  
Strategy for generating `twisted.python.url` URLs.

**txacme.test.test\_challenges module** Tests for `txacme.challenges`.

**class** txacme.test.test\_challenges.**HTTPResponderTests** (*\*args*, *\*\*kwargs*)  
`HTTP01Responder` is a responder for http-01 challenges.

**test\_start\_responding** ()  
Calling `start_responding` makes an appropriate resource available.

```
class txacme.test.test_challenges.TLSResponderTests (*args, **kwargs)
    TLSSNI01Responder is a responder for tls-sni-01 challenges that works with txsni.

    test_start_responding ()
        Calling start_responding makes an appropriate entry appear in the host map.

class txacme.test.test_challenges.MergingProxyTests (*args, **kwargs)
    _MergingMappingProxy merges two mappings together.

    test_contains ()
        The mapping only contains a key if it can be gotten.

    test_get_both ()
        Getting an key that exists in both the underlay and the overlay returns the value from the overlay.

    test_get_overlay ()
        Getting an key that only exists in the overlay returns the value from the overlay.

    test_get_underlay ()
        Getting an key that only exists in the underlay returns the value from the underlay.

    test_iter ()
        __iter__ of the proxy does not produce duplicate keys.

    test_len ()
        __len__ of the proxy does not count duplicates.

class txacme.test.test_challenges.LibcloudResponderTests (*args, **kwargs)
    LibcloudDNSResponder implements a responder for dns-01 challenges using libcloud on the backend.

    test_auto_zone ()
        If the configured zone_name is None, the zone will be guessed by finding the longest zone that is a suffix
        of the server name.

    test_auto_zone_missing ()
        If the configured zone_name is None, and no matching zone is found, NotInZone is raised.

    test_daemon_threads ()
        _daemon_thread creates thread objects with daemon set.

    test_missing_zone ()
        ZoneNotFound is raised if the configured zone cannot be found at the configured provider.

    test_start_responding ()
        Calling start_responding causes an appropriate TXT record to be created.

    test_wrong_zone ()
        Trying to respond for a domain not in the configured zone results in a NotInZone exception.

txacme.test.test_client module
class txacme.test.test_client.ClientTests (*args, **kwargs)
    Client provides a client interface for the ACME API.

    test_agree_to_tos ()
        Agreeing to the TOS returns a registration with the agreement updated.

    test_answer_challenge ()
        answer_challenge responds to a challenge and returns the updated challenge.

    test_answer_challenge_function ()
        The challenge is found in the responder after invoking answer_challenge.
```

**test\_authorization\_missing\_link()**  
    *\_parse\_authorization* raises *ClientError* if the "next" link is missing.

**test\_authorization\_unexpected\_identifier()**  
    *\_check\_authorization* raises *UnexpectedUpdate* if the return identifier doesn't match.

**test\_challenge\_missing\_link()**  
    *\_parse\_challenge* raises *ClientError* if the "up" link is missing.

**test\_challenge\_unexpected\_uri()**  
    *\_check\_challenge* raises *UnexpectedUpdate* if the challenge does not have the expected URI.

**test\_default\_client()**  
    ~txacme.client.\_default\_client constructs a client if one was not provided.

**test\_directory\_url\_type()**  
    *from\_url* expects a *twisted.python.url.URL* instance for the url argument.

**test\_expect\_response\_wrong\_code()**  
    *\_expect\_response* raises *ClientError* if the response code does not match the expected code.

**test\_fetch\_chain\_empty()**  
    If a certificate has no issuer link, *Client.fetch\_chain* returns an empty chain.

**test\_fetch\_chain\_okay()**  
    A certificate chain that is shorter than the max length is returned.

**test\_fetch\_chain\_too\_long()**  
    A certificate chain that is too long fails with *ClientError*.

**test\_fqdn\_identifier()**  
    *fqdn\_identifier* constructs an *Identifier* of the right type.

**test\_from\_directory()**  
    *from\_url()* constructs a client with a directory retrieved from the given URL.

**test\_no\_tls\_sni\_01()**  
    If no tls-sni-01 challenges are available, *NoSupportedChallenges* is raised.

**test\_only\_tls\_sni\_01()**  
    If a singleton tls-sni-01 challenge is available, it is returned.

**test\_poll()**  
    *poll* retrieves the latest state of an authorization resource, as well as the minimum time to wait before polling the state again.

**test\_poll\_invalid()**  
    If the authorization enters an invalid state while polling, *poll\_until\_valid* will fail with *AuthorizationFailed*.

**test\_poll\_timeout()**  
    If the timeout is exceeded during polling, *poll\_until\_valid* will fail with *CancelledError*.

**test\_poll\_valid()**  
    If the authorization enters a valid state while polling, *poll\_until\_valid* will fire with the updated authorization.

**test\_register()**  
    If the registration succeeds, the new registration is returned.

**test\_register\_bad\_nonce\_once()**  
    If a badNonce error is received, we clear all old nonces and retry the request once.

**test\_register\_bad\_nonce\_twice()**

If a badNonce error is received on a retry, fail the request.

**test\_register\_error()**

If some other error occurs during registration, a `txacme.client.ServerError` results.

**test\_register\_existing()**

If registration fails due to our key already being registered, the existing registration is returned.

**test\_register\_existing\_update()**

If registration fails due to our key already being registered, the existing registration is updated.

**test\_register\_missing\_next()**

If the directory does not return a "next" link, a `ClientError` failure occurs.

**test\_request\_challenges()**

`request_challenges()` creates a new authorization, and returns the authorization resource with a list of possible challenges to proceed with.

**test\_request\_issuance()**

If issuing is successful, a certificate resource is returned.

**test\_tls\_sni\_01\_no\_singleton()**

If a suitable singleton challenge is not found, `NoSupportedChallenges` is raised.

**test\_unexpected\_update()**

If the server does not return the registration we expected, an `UnexpectedUpdate` failure occurs.

**class txacme.test.test\_client.ExtraCoverageTests(\*args, \*\*kwargs)**

Tests to get coverage on some test helpers that we don't really want to maintain ourselves.

**test\_consume\_context\_manager\_fails\_on\_remaining\_requests()**

If the consume context manager is used, if there are any remaining expecting requests, the test case will be failed.

**test\_unexpected\_number\_of\_request\_causes\_failure()**

If there are no more expected requests, making a request causes a failure.

**class txacme.test.test\_client.LinkParsingTests(\*args, \*\*kwargs)**

`_parse_header_links` parses the links from a response with Link: header fields. This implementation is ... actually not very good, which is why there aren't many tests.

**test\_rfc\_example1()**

The first example from the RFC.

**txacme.test.test\_endpoint module** Tests for `txacme.endpoint`.

**class txacme.test.test\_endpoint.EndpointTests(\*args, \*\*kwargs)**

Tests for `AutoTLSEndpoint`.

**test\_directory\_url\_type()**

`AutoTLSEndpoint` expects a `twisted.python.url.URL` instance for the directory argument.

**test\_listen\_starts\_service()**

`AutoTLSEndpoint.listen` starts an `AcmeIssuingService`. Stopping the port stops the service.

**class txacme.test.test\_endpoint.PluginTests(\*args, \*\*kwargs)**

Tests for the plugins.

**test\_le\_parser()**

The `le:` parser uses the Let's Encrypt production directory, and provides the relevant interfaces.

**test\_lets\_parser()**

The `lets: parser` uses the Let's Encrypt staging directory, and provides the relevant interfaces.

**test\_parser()**

`AcmeParser` creates an endpoint with the specified ACME directory and directory store.

**txacme.test.test\_matchers module**

**class** `txacme.test.test_matchers.ValidForNameTests(*args, **kwargs)`

*ValidForName* matches if a CSR/cert is valid for the given name.

**txacme.test.test\_service module**

**class** `txacme.test.test_service.AcmeIssuingServiceTests(*args, **kwargs)`

Tests for `txacme.service.AcmeIssuingService`.

**test\_blank\_cert()**

An empty certificate file will be treated like an expired certificate.

**test\_cancellation()**

Cancelling the deferred returned by `issue_cert` cancels the actual issuing process.

**test\_default\_panic()**

The default panic callback logs a message via `twisted.logger`.

**test\_errors()**

If a cert renewal fails within the panic interval, the panic callback is invoked; otherwise the error is logged normally.

**test\_issue\_concurrently()**

Invoking `issue_cert` multiple times concurrently for the same name will not start multiple issuing processes, only wait for the first process to complete.

**test\_issue\_one\_cert()**

`issue_cert` will (re)issue a single certificate unconditionally.

**test\_registration\_email()**

If we give our service an email address, that address will be used as a registration contact.

**test\_starting\_stopping\_cancellation()**

Test the starting and stopping behaviour.

**test\_time\_marches\_on()**

Any certs that have exceeded the panic or reissue intervals will be reissued at the next check.

**test\_timer\_errors()**

If the timed check fails (for example, because registration fails), the error should be caught and logged.

**test\_when\_certs\_valid\_all\_certs\_valid()**

The deferred returned by `when_certs_valid` fires immediately if none of the certs in the store are expired.

**test\_when\_certs\_valid\_certs\_expired()**

The deferred returned by `when_certs_valid` only fires once all panicing and expired certs have been renewed.

**test\_when\_certs\_valid\_no\_certs()**

The deferred returned by `when_certs_valid` fires immediately if there are no certs in the store.

### txacme.test.test\_store module

**class** txacme.test.test\_store.**DirectoryStoreTests** (\*args, \*\*kwargs)  
Tests for *txacme.store.DirectoryStore*.

**test\_filepath\_mode** ()  
The given `FilePath` is always converted to text mode.

**class** txacme.test.test\_store.**MemoryStoreTests** (\*args, \*\*kwargs)  
Tests for *txacme.testing.MemoryStore*.

### txacme.test.test\_util module

**class** txacme.test.test\_util.**GeneratePrivateKeyTests** (\*args, \*\*kwargs)  
*generate\_private\_key* generates private keys of various types using sensible parameters.

**test\_rsa\_key** ()  
Passing `u'rsa'` results in an RSA private key.

**test\_unknown\_key\_type** ()  
Passing an unknown key type results in `ValueError`.

**class** txacme.test.test\_util.**GenerateCertTests** (\*args, \*\*kwargs)  
*generate\_tls\_sni\_01\_cert* generates a cert and key suitable for responding for the given challenge SAN.

**test\_cert\_verifies** ()  
The certificates generated verify using *verify\_cert*.

**class** txacme.test.test\_util.**CSRTests** (\*args, \*\*kwargs)  
*encode\_csr* and *decode\_csr* serialize CSRs in JOSE Base64 DER encoding.

**test\_common\_name\_too\_long** ()  
If the first name provided is too long, *csr\_for\_names* uses a dummy value for the common name.

**test\_decode\_garbage** ()  
If decoding fails, *decode\_csr* raises `DeserializationError`.

**test\_empty\_names\_invalid** ()  
*csr\_for\_names* raises `ValueError` if given an empty list of names.

**test\_roundtrip** ()  
The encoding roundtrips.

**test\_valid\_for\_names** ()  
*csr\_for\_names* returns a CSR that is actually valid for the given names.

**class** txacme.test.test\_util.**ConstTests** (\*args, \*\*kwargs)  
*const* returns a function that always returns a constant value.

## Module contents

### Submodules

#### txacme.client module

ACME client API (like *acme.client*) implementation for Twisted.

**class** txacme.client.**Client** (*directory, reactor, key, jws\_client*)  
ACME client interface.

**agree\_to\_tos** (*regr*)

Accept the terms-of-service for a registration.

**Parameters** **regr** (*RegistrationResource*) – The registration to update.

**Returns** The updated registration resource.

**Return type** Deferred[*RegistrationResource*]

**answer\_challenge** (*challenge\_body, response*)

Respond to an authorization challenge.

**Parameters**

- **challenge\_body** (*ChallengeBody*) – The challenge being responded to.
- **response** (*ChallengeResponse*) – The response to the challenge.

**Returns** The updated challenge resource.

**Return type** Deferred[*ChallengeResource*]

**fetch\_chain** (*cert, max\_length=10*)

Fetch the intermediary chain for a certificate.

**Parameters**

- **cert** (*acme.messages.CertificateResource*) – The certificate to fetch the chain for.
- **max\_length** (*int*) – The maximum length of the chain that will be fetched.

**Return type** Deferred[List[*acme.messages.CertificateResource*]]

**Returns** The issuer certificate chain, ordered with the trust anchor last.

**classmethod from\_url** (*reactor, url, key, alg=RS256, jws\_client=None*)

Construct a client from an ACME directory at a given URL.

**Parameters**

- **url** – The `twisted.python.url.URL` to fetch the directory from. See `txacme.urls` for constants for various well-known public directories.
- **reactor** – The Twisted reactor to use.
- **key** (*JWK*) – The client key to use.
- **alg** – The signing algorithm to use. Needs to be compatible with the type of key used.
- **jws\_client** (*JWSClient*) – The underlying client to use, or `None` to construct one.

**Returns** The constructed client.

**Return type** Deferred[*Client*]

**poll** (*authzr*)

Update an authorization from the server (usually to check its status).

**register** (*new\_reg=None*)

Create a new registration with the ACME server.

**Parameters** **new\_reg** (*NewRegistration*) – The registration message to use, or `None` to construct one.

**Returns** The registration resource.

**Return type** Deferred[*RegistrationResource*]

**request\_challenges** (*identifier*)

Create a new authorization.

**Parameters** **identifier** (*Identifier*) – The identifier to authorize.

**Returns** The new authorization resource.

**Return type** Deferred[AuthorizationResource]

**request\_issuance** (*csr*)

Request a certificate.

Authorizations should have already been completed for all of the names requested in the CSR.

Note that unlike `acme.client.Client.request_issuance`, the certificate resource will have the body data as raw bytes.

**See also:**

`txacme.util.csr_for_names`

---

### Todo

Delayed issuance is not currently supported, the server must issue the requested certificate immediately.

---

**Parameters** **csr** – A certificate request message: normally `txacme.messages.CertificateRequest` or `acme.messages.CertificateRequest`.

**Return type** Deferred[acme.messages.CertificateResource]

**Returns** The issued certificate.

**classmethod** **retry\_after** (*response*, *default=5*, *\_now=<built-in function time>*)

Parse the Retry-After value from a response.

**update\_registration** (*reg*, *uri=None*)

Submit a registration to the server to update it.

**Parameters**

- **reg** (*RegistrationResource*) – The registration to update. Can be a `NewRegistration` instead, in order to create a new registration.
- **uri** (*str*) – The url to submit to. Must be specified if a `NewRegistration` is provided.

**Returns** The updated registration resource.

**Return type** Deferred[RegistrationResource]

**class** `txacme.client.JWSClient` (*req\_client*, *key*, *alg*, *user\_agent='txacme/0.9.1+2.g9b52744.dirty'*)  
HTTP client using JWS-signed messages.

**get** (*url*, *content\_type='application/json'*, *\*\*kwargs*)

Send GET request and check response.

**Parameters**

- **method** (*str*) – The HTTP method to use.
- **url** (*str*) – The URL to make the request to.

**Raises**

- `txacme.client.ServerError` – If server response body carries HTTP Problem (draft-ietf-appsawg-http-problem-00).
- `acme.errors.ClientError` – In case of other protocol errors.

**Returns** Deferred firing with the checked HTTP response.

**head** (*url*, \**args*, \*\**kwargs*)

Send HEAD request without checking the response.

Note that `_check_response` is not called, as there will be no response body to check.

**Parameters** `url` (*str*) – The URL to make the request to.

**post** (*url*, *obj*, *content\_type*=`'application/json'`, \*\**kwargs*)

POST an object and check the response. Retry once if a badNonce error is received.

#### Parameters

- `url` (*str*) – The URL to request.
- `obj` (*JSONDeSerializable*) – The serializable payload of the request.
- `content_type` (*bytes*) – The expected content type of the response. By default, JSON.

#### Raises

- `txacme.client.ServerError` – If server response body carries HTTP Problem (draft-ietf-appsawg-http-problem-00).
- `acme.errors.ClientError` – In case of other protocol errors.

**exception** `txacme.client.ServerError` (*message*, *response*)

`acme.messages.Error` isn't usable as an asynchronous exception, because it doesn't allow setting the `__traceback__` attribute like Twisted wants to do when cleaning Failures. This type exists to wrap such an error, as well as provide access to the original response.

`txacme.client.fqdn_identifier` (*fqdn*)

Construct an identifier from an FQDN.

Trivial implementation, just saves on typing.

**Parameters** `fqdn` (*str*) – The domain name.

**Returns** The identifier.

**Return type** `Identifier`

`txacme.client.answer_challenge` (*authzr*, *client*, *responders*)

Complete an authorization using a responder.

#### Parameters

- `auth` (*AuthorizationResource*) – The authorization to complete.
- `client` (*Client*) – The ACME client.
- `responders` (*List[IResponder]*) – A list of responders that can be used to complete the challenge with.

**Returns** A deferred firing when the authorization is verified.

`txacme.client.poll_until_valid` (*authzr*, *clock*, *client*, *timeout*=`300.0`)

Poll an authorization until it is in a state other than pending or processing.

#### Parameters

- **auth** (*AuthorizationResource*) – The authorization to complete.
- **clock** – The `IReactorTime` implementation to use; usually the reactor, when not testing.
- **client** (*Client*) – The ACME client.
- **timeout** (*float*) – Maximum time to poll in seconds, before giving up.

**Raises** `txacme.client.AuthorizationFailed` – if the authorization is no longer in the pending, processing, or valid states.

**Raises** `twisted.internet.defer.CancelledError` if the authorization was still in pending or processing state when the timeout was reached.

**Return type** `Deferred[AuthorizationResource]`

**Returns** A deferred firing when the authorization has completed/failed; if the authorization is valid, the authorization resource will be returned.

**exception** `txacme.client.NoSupportedChallenges`

No supported challenges were found in an authorization.

**exception** `txacme.client.AuthorizationFailed` (*authzr*)

An attempt was made to complete an authorization, but it failed.

## txacme.endpoint module

A TLS endpoint that supports SNI automatically issues / renews certificates via an ACME CA (eg. Let's Encrypt).

```
class txacme.endpoint.AutoTLSEndpoint (reactor,          directory,          client_creator,
                                       cert_store,       cert_mapping,       sub_endpoint,
                                       check_interval=datetime.timedelta(1),
                                       reissue_interval=datetime.timedelta(30),
                                       panic_interval=datetime.timedelta(15), panic=<function
                                       _default_panic>,      generate_key=<functools.partial
                                       object>)
```

A server endpoint that does TLS SNI, with certificates automatically (re)issued from an ACME certificate authority.

### Parameters

- **reactor** – The Twisted reactor.
- **directory** – `twisted.python.url.URL` for the ACME directory to use for issuing certs.
- **client\_creator** (`Callable[[reactor, twisted.python.url.URL], Deferred[txacme.client.Client]]`) – A callable called with the reactor and directory URL for creating the ACME client. For example, `partial(Client.from_url, key=acme_key, alg=RS256)`.
- **cert\_store** (`ICertificateStore`) – The certificate store containing the certificates to manage. For example, `txacme.store.DirectoryStore`.
- **cert\_mapping** (*dict*) – The certificate mapping to use for SNI; for example, `txsni.snimap.HostDirectoryMap`. Usually this should correspond to the same underlying storage as `cert_store`.
- **check\_interval** (*timedelta*) – How often to check for expiring certificates.

- **reissue\_interval** (*timedelta*) – If a certificate is expiring in less time than this interval, it will be reissued.
- **panic\_interval** (*timedelta*) – If a certificate is expiring in less time than this interval, and reissuing fails, the panic callback will be invoked.
- **panic** (Callable[[Failure, str], Deferred]) – A callable invoked with the failure and server name when reissuing fails for a certificate expiring in the `panic_interval`. For example, you could generate a monitoring alert. The default callback logs a message at *CRITICAL* level.
- **generate\_key** – A 0-arg callable used to generate a private key for a new cert. Normally you would not pass this unless you have specialized key generation requirements.

**listen** (*protocolFactory*)

Start an issuing service, and wait until initial issuing is complete.

`txacme.endpoint.load_or_create_client_key` (*pem\_path*)

Load the client key from a directory, creating it if it does not exist.

---

**Note:** The client key that will be created will be a 2048-bit RSA key.

---

**Parameters** `pem_path` (`twisted.python.filepath.FilePath`) – The certificate directory to use, as with the endpoint.

## txacme.errors module

Exception types for txacme.

**exception** `txacme.errors.NotInZone` (*server\_name, zone\_name*)

The given domain name is not in the configured zone.

**exception** `txacme.errors.ZoneNotFound` (*zone\_name*)

The configured zone was not found in the zones at the configured provider.

## txacme.interfaces module

Interface definitions for txacme.

**interface** `txacme.interfaces.IResponder`

Configuration for a ACME challenge responder.

The actual responder may exist somewhere else, this interface is merely for an object that knows how to configure it.

**challenge\_type**

The type of challenge this responder is able to respond for.

Must correspond to one of the types from `acme.challenges`; for example, `u'tls-sni-01'`.

**stop\_responding** (*server\_name, challenge, response*)

Stop responding for a particular challenge.

May be a noop if a particular responder does not need or implement explicit cleanup; implementations should not rely on this method always being called.

**Parameters**

- **server\_name** (*str*) – The server name for which the challenge is being completed.
- **challenge** – The `acme.challenges` challenge object; the exact type of this object depends on the challenge type.
- **response** – The `acme.challenges` response object; the exact type of this object depends on the challenge type.

**start\_responding** (*server\_name, challenge, response*)

Start responding for a particular challenge.

**Parameters**

- **server\_name** (*str*) – The server name for which the challenge is being completed.
- **challenge** – The `acme.challenges` challenge object; the exact type of this object depends on the challenge type.
- **response** – The `acme.challenges` response object; the exact type of this object depends on the challenge type.

**Return type** `Deferred`

**Returns** A deferred firing when the challenge is ready to be verified.

**interface** `txacme.interfaces.ICertificateStore`

A store of certificate/keys/chains.

**as\_dict** (*self*)

Get all certificates in the store.

**Return type** `Deferred[Dict[str, List[:ref: 'pem-objects']]]`

**Returns** A deferred firing with a dict mapping server names to [PEM Objects](#).

**store** (*self, server\_name, pem\_objects*)

Store PEM objects for the given server name.

Implementations do not have to permit invoking this with a server name that was not already present in the store.

**Parameters**

- **server\_name** (*str*) – The server name to update.
- **pem\_objects** – A list of [PEM Objects](#); must contain exactly one private key, a certificate corresponding to that private key, and zero or more chain certificates.

**Return type** `Deferred`

**get** (*self, server\_name*)

Retrieve the current PEM objects for the given server name.

**Parameters** **server\_name** (*str*) – The server name.

**Raises** [KeyError](#) – if the given name does not exist in the store.

**Returns** `Deferred[List[:ref: 'pem-objects']]`

## txacme.logging module

Eliot message and action definitions.

## txacme.messages module

ACME protocol messages.

This module provides supplementary message implementations that are not already provided by the `acme` library.

### See also:

`acme.messages`

**class** `txacme.messages.CertificateRequest` (*\*\*kwargs*)

ACME new-cert request.

Differs from the upstream version because it wraps a Cryptography CSR object instead of a PyOpenSSL one.

### See also:

`acme.messages.CertificateRequest`, `cryptography.x509.CertificateSigningRequest`

## txacme.service module

**class** `txacme.service.AcmeIssuingService` (*cert\_store, client\_creator, clock, responders, email=None, check\_interval=datetime.timedelta(1), reissue\_interval=datetime.timedelta(30), panic\_interval=datetime.timedelta(15), panic=<function \_default\_panic>, generate\_key=<functools.partial object>*)

A service for keeping certificates up to date by using an ACME server.

### Parameters

- **cert\_store** (`ICertificateStore`) – The certificate store containing the certificates to manage.
- **client\_creator** (`Callable[[], Deferred[txacme.client.Client]]`) – A callable called with no arguments for creating the ACME client. For example, `partial(Client.from_url, reactor=reactor, url=LETSENCRYPT_STAGING_DIRECTORY, key=acme_key, alg=RS256)`.
- **clock** – `IReactorTime` provider; usually the reactor, when not testing.
- **responders** (`List[IResponder]`) – Challenge responders. Usually only one responder is needed; if more than one responder for the same type is provided, only the first will be used.
- **email** (*str*) – An (optional) email address to use during registration.
- **check\_interval** (*timedelta*) – How often to check for expiring certificates.
- **reissue\_interval** (*timedelta*) – If a certificate is expiring in less time than this interval, it will be reissued.
- **panic\_interval** (*timedelta*) – If a certificate is expiring in less time than this interval, and reissuing fails, the panic callback will be invoked.
- **panic** (`Callable[[Failure, str], Deferred]`) – A callable invoked with the failure and server name when reissuing fails for a certificate expiring in the `panic_interval`. For example, you could generate a monitoring alert. The default callback logs a message at `CRITICAL` level.
- **generate\_key** – A 0-arg callable used to generate a private key for a new cert. Normally you would not pass this unless you have specialized key generation requirements.

**issue\_cert** (*server\_name*)

Issue a new cert for a particular name.

If an existing cert exists, it will be replaced with the new cert. If issuing is already in progress for the given name, a second issuing process will *not* be started.

**Parameters** **server\_name** (*str*) – The name to issue a cert for.

**Return type** `Deferred`

**Returns** A deferred that fires when issuing is complete.

**when\_certs\_valid** ()

Get a notification once the startup check has completed.

When the service starts, an initial check is made immediately; the deferred returned by this function will only fire once reissue has been attempted for any certificates within the panic interval.

---

**Note:** The reissue for any of these certificates may not have been successful; the panic callback will be invoked for any certificates in the panic interval that failed reissue.

---

**Return type** `Deferred`

**Returns** A deferred that fires once the initial check has resolved.

## txacme.store module

txacme.interfaces.ICertificateStore implementations.

**class** txacme.store.**DirectoryStore** (*path*)

A certificate store that keeps certificates in a directory on disk.

## txacme.testing module

Utilities for testing with txacme.

**class** txacme.testing.**FakeClient** (*key, clock, ca\_key=None, controller=None*)

Provides the same API as *Client*, but performs no network operations and issues certificates signed by its own fake CA.

**class** txacme.testing.**FakeClientController** (*paused=False*)

Controls issuing for *FakeClient*.

**count** ()

Count pending issuances.

**issue** ()

Return a deferred that fires when we are ready to issue.

**pause** ()

Temporarily pause issuing.

**resume** ()

Resume issuing, allowing any pending issuances to proceed.

**class** txacme.testing.**MemoryStore** (*certs=None*)

A certificate store that keeps certificates in memory only.

**class** `txacme.testing.NullResponder` (*challenge\_type*)  
 A responder that does absolutely nothing.

## txacme.urls module

## txacme.util module

Utility functions that may prove useful when writing an ACME client.

`txacme.util.generate_private_key` (*key\_type*)  
 Generate a random private key using sensible parameters.

**Parameters** `key_type` (*str*) – The type of key to generate. One of: `rsa`.

`txacme.util.generate_tls_sni_01_cert` (*server\_name*, *key\_type=u'rsa'*, *\_generate\_private\_key=None*)  
 Generate a certificate/key pair for responding to a tls-sni-01 challenge.

### Parameters

- **server\_name** (*str*) – The SAN the certificate should have.
- **key\_type** (*str*) – The type of key to generate; usually not necessary.

**Return type** `Tuple[~cryptography.x509.Certificate, PrivateKey]`

**Returns** A tuple of the certificate and private key.

`txacme.util.cert_cryptography_to_pyopenssl` (*cert*)  
 Convert a `cryptography.x509.Certificate` object to an `OpenSSL.crypto.X509` object.

`txacme.util.key_cryptography_to_pyopenssl` (*key*)  
 Convert a `Cryptography` private key object to an `OpenSSL.crypto.PKey` object.

`txacme.util.tap` (*f*)  
 “Tap” a `Deferred` callback chain with a function whose return value is ignored.

`txacme.util.encode_csr` (*csr*)  
 Encode CSR as JOSE Base-64 DER.

**Parameters** `csr` (`cryptography.x509.CertificateSigningRequest`) – The CSR.

**Return type** `str`

`txacme.util.decode_csr` (*b64der*)  
 Decode JOSE Base-64 DER-encoded CSR.

**Parameters** `b64der` (*str*) – The encoded CSR.

**Return type** `cryptography.x509.CertificateSigningRequest`

**Returns** The decoded CSR.

`txacme.util.csr_for_names` (*names, key*)  
 Generate a certificate signing request for the given names and private key.

### See also:

`acme.client.Client.request_issuance`

### See also:

`generate_private_key`

**Parameters**

- **List [str]** – One or more names (subjectAltName) for which to request a certificate.
- **key** – A Cryptography private key object.

**Return type** `cryptography.x509.CertificateSigningRequest`

**Returns** The certificate request message.

`txacme.util.clock_now` (*clock*)

Get a datetime representing the current time.

**Parameters** **clock** – An `IReactorTime` provider.

**Return type** `datetime`

**Returns** A datetime representing the current time.

`txacme.util.check_directory_url_type` (*url*)

Check that `url` is a `twisted.python.url.URL` instance, raising `TypeError` if it isn't.

`txacme.util.const` (*x*)

Return a constant function.
