1 Video course

2 Migrate to v0.11 (Add-in)
   2.1 Upgrade the xlwings Python package
   2.2 Install the add-in
   2.3 Upgrade existing workbooks

3 Migrate to v0.9
   3.1 Full qualification: Using collections
   3.2 Connecting to Books
   3.3 Active Objects
   3.4 Round vs. Square Brackets
   3.5 Access the underlying Library/Engine
   3.6 Cheat sheet

4 Installation
   4.1 Dependencies
   4.2 Optional Dependencies
   4.3 Add-in
   4.4 Python version support

5 Quickstart
   5.1 1. Scripting: Automate/interact with Excel from Python
   5.2 2. Macros: Call Python from Excel
   5.3 3. UDFs: User Defined Functions (Windows only)

6 Connect to a Book
   6.1 Python to Excel
   6.2 Excel to Python (RunPython)
   6.3 User Defined Functions (UDFs)

7 Syntax Overview
   7.1 Active Objects
Those who prefer a didactically structured video course over this documentation should have a look at our video course:

https://training.zoomeranalytics.com/p/xlwings

It’s also a great way to support the ongoing development of xlwings :)
Migrate to v0.11 (Add-in)

This migration guide shows you how you can start using the new xlwings add-in as opposed to the old xlwings VBA module (and the old add-in that consisted of just a single import button).

2.1 Upgrade the xlwings Python package

1. Check where xlwings is currently installed

   ```python
   >>> import xlwings
   >>> xlwings.__path__
   ```

2. If you installed xlwings with pip, for once, you should first uninstall xlwings: `pip uninstall xlwings`

3. Check the directory that you got under 1): if there are any files left over, delete the `xlwings` folder and the remaining files manually

4. Install the latest `xlwings` version: `pip install xlwings`

5. Verify that you have >= 0.11 by doing

   ```python
   >>> import xlwings
   >>> xlwings.__version__
   ```

2.2 Install the add-in

1. If you have the old xlwings addin installed, find the location and remove it or overwrite it with the new version (see next step). If you installed it via the xlwings command line client, you should be
able to do: `xlwings addin remove`.

2. Close Excel. Run `xlwings addin install` from a command prompt. Reopen Excel and check if the xlwings Ribbon appears. If not, copy `xlwings.xlam` (from your xlwings installation folder under `addin\xlwings.xlam`) manually into the `XLSTART` folder. You can find the location of this folder under Options > Trust Center > Trust Center Settings... > Trusted Locations, under the description Excel default location: User StartUp. Restart Excel and you should see the add-in.

### 2.3 Upgrade existing workbooks

1. Make a backup of your Excel file
2. Open the file and go to the VBA Editor (Alt-F11)
3. Remove the xlwings VBA module
4. Add a reference to the xlwings addin, see *Installation*
5. If you want to use workbook specific settings, add a sheet `xlwings.conf`, see *Workbook Config: xlwings.conf Sheet*

**Note:** To import UDFs, you need to have the reference to the xlwings add-in set!
The purpose of this document is to enable you a smooth experience when upgrading to xlwings v0.9.0 and above by laying out the concept and syntax changes in detail. If you want to get an overview of the new features and bug fixes, have a look at the release notes. Note that the syntax for User Defined Functions (UDFs) didn’t change.

### 3.1 Full qualification: Using collections

The new object model allows to specify the Excel application instance if needed:

- **old**: `xw.Range('Sheet1', 'A1', wkb=xw.Workbook('Book1'))`
- **new**: `xw.apps[0].books['Book1'].sheets['Sheet1'].range('A1')`

See *Syntax Overview* for the details of the new object model.

### 3.2 Connecting to Books

- **old**: `xw.Workbook()`
- **new**: `xw.Book()` or `xw.books` if you need to control the app instance.

See *Connect to a Book* for the details.
### 3.3 Active Objects

```python
# Active app (i.e. Excel instance)
>>> app = xw.apps.active

# Active book
>>> wb = xw.books.active  # in active app
>>> wb = app.books.active  # in specific app

# Active sheet
>>> sht = xw.sheets.active  # in active book
>>> sht = wb.sheets.active  # in specific book

# Range on active sheet
>>> xw.Range('A1')  # on active sheet of active book of active app
```

### 3.4 Round vs. Square Brackets

Round brackets follow Excel’s behavior (i.e. 1-based indexing), while square brackets use Python’s 0-based indexing/slicing.

As an example, the following all reference the same range:

```plaintext
xw.apps[0].books[0].sheets[0].range('A1')
xw.apps(1).books(1).sheets(1).range('A1')
xw.apps[0].books['Book1'].sheets['Sheet1'].range('A1')
xw.apps(1).books('Book1').sheets('Sheet1').range('A1')
```

### 3.5 Access the underlying Library/Engine

- **old**: `xw.Range('A1').xl_range` and `xl_sheet` etc.
- **new**: `xw.Range('A1').api`, same for all other objects

This returns a `pywin32` COM object on Windows and an `appscript` object on Mac.

### 3.6 Cheat sheet

Note that `sht` stands for a sheet object, like e.g. (in 0.9.0 syntax): `sht = xw.books['Book1'].sheets[0]`
Table 1 – continued from previous page

<table>
<thead>
<tr>
<th>Get app from book</th>
<th>app = wb.app</th>
<th>app = xw.Application(wb)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target installation (Mac)</td>
<td>app = xw.App(spec=...)</td>
<td>wb = xw.Workbook(app)</td>
</tr>
<tr>
<td>Hide Excel Instance</td>
<td>app = xw.App(Visible=False)</td>
<td>wb = xw.Workbook(app)</td>
</tr>
<tr>
<td>Selected Range</td>
<td>app.selection</td>
<td>wb.get_selection()</td>
</tr>
<tr>
<td>Calculation mode</td>
<td>app.calculation = 'manual'</td>
<td>app.calculation = 'manual'</td>

<td>xw.Range(sht, 'A1').name = 'name'</td>
</tr>
<tr>
<td>Get name of range</td>
<td>sht.range('A1').name</td>
<td>xw.Range(sht, 'A1').name</td>
</tr>
<tr>
<td>mock caller</td>
<td>xw.Book('file.xlsm').set_mock_caller()</td>
<td>xw.Workbook.set_mock_caller('file.xlsm')</td>
</tr>
</tbody>
</table>
The easiest way to install xlwings is via pip:

```
pip install xlwings
```

or conda:

```
conda install xlwings
```

Note that the official conda package might be few releases behind. You can, however, use the conda-forge channel (see: https://anaconda.org/conda-forge/xlwings) which should usually be up to date (but might still be a day or so behind the pip release):

```
conda install -c conda-forge xlwings
```

**Note:** When you are using Mac Excel 2016 and are installing xlwings with conda (or use the version that comes with Anaconda), you’ll need to run `$ xlwings runpython install` once to enable the RunPython calls from VBA. Alternatively, you can simply install xlwings with pip.

### 4.1 Dependencies

- **Windows:** pywin32, comtypes
  
  On Windows, the dependencies are automatically being handled if xlwings is installed with conda or pip.

- **Mac:** psutil, appscript
On Mac, the dependencies are automatically being handled if xlwings is installed with conda or pip. However, with pip, the Xcode command line tools need to be available. Mac OS X 10.4 (Tiger) or later is required. The recommended Python distribution for Mac is Anaconda.

4.2 Optional Dependencies

- NumPy
- Pandas
- Matplotlib
- Pillow/PIL

These packages are not required but highly recommended as they play very nicely with xlwings.

4.3 Add-in

Please see Add-in on how to install the xlwings add-in.

4.4 Python version support

xlwings is tested on Python 2.7 and 3.3+
Quickstart

This guide assumes you have xlwings already installed. If that’s not the case, head over to Installation.

5.1 1. Scripting: Automate/interact with Excel from Python

Establish a connection to a workbook:

```python
>>> import xlwings as xw
>>> wb = xw.Book()  # this will create a new workbook
>>> wb = xw.Book('FileName.xlsx')  # connect to an existing file in the current working directory
>>> wb = xw.Book(r'C:\path\to\file.xlsx')  # on Windows: use raw strings to escape backslashes
```

If you have the same file open in two instances of Excel, you need to fully qualify it and include the app instance:

```python
>>> xw.apps[0].books['FileName.xlsx']
```

Instantiate a sheet object:

```python
>>> sht = wb.sheets['Sheet1']
```

Reading/writing values to/from ranges is as easy as:

```python
>>> sht.range('A1').value = 'Foo 1'
>>> sht.range('A1').value
'Foo 1'
```

There are many convenience features available, e.g. Range expanding:
Powerful converters handle most data types of interest, including Numpy arrays and Pandas DataFrames in both directions:

```python
>>> import pandas as pd
>>> df = pd.DataFrame([[1,2], [3,4]], columns=['a', 'b'])
>>> sht.range('A1').value = df
>>> sht.range('A1').options(pd.DataFrame, expand='table').value
   a  b
0.0 1.0 2.0
1.0 3.0 4.0
```

Matplotlib figures can be shown as pictures in Excel:

```python
>>> import matplotlib.pyplot as plt

>>> fig = plt.figure()
>>> plt.plot([1, 2, 3, 4, 5])
[<matplotlib.lines.Line2D at 0x1071706a0>]

>>> sht.pictures.add(fig, name='MyPlot', update=True)
Picture 'MyPlot' in <Sheet [Workbook4]Sheet1>
```

Shortcut for the active sheet: `xw.Range`

If you want to quickly talk to the active sheet in the active workbook, you don’t need instantiate a workbook and sheet object, but can simply do:

```python
>>> import xlwings as xw

>>> xw.Range('A1').value = 'Foo'
>>> xw.Range('A1').value
'Foo'
```

Note: You should only use `xw.Range` when interacting with Excel. In scripts, you should always go via book and sheet objects as shown above.

## 5.2 2. Macros: Call Python from Excel

You can call Python functions from VBA using the `RunPython` function:

```vba
Sub HelloWorld()
    RunPython ("import hello; hello.world()")
End Sub
```

Per default, `RunPython` expects `hello.py` in the same directory as the Excel file. Refer to the calling Excel book by using `xw.Book.caller:`
To make this run, you’ll need to have the xlwings add-in installed. The easiest way to get everything set up is to use the xlwings command line client from either a command prompt on Windows or a terminal on Mac: `xlwings quickstart myproject`.

For details about the addin, see Add-in.

5.3 3. UDFs: User Defined Functions (Windows only)

Writing a UDF in Python is as easy as:

```python
import xlwings as xw

@xw.func
def hello(name):
    return 'Hello {0}'.format(name)
```

Converters can be used with UDFs, too. Again a Pandas DataFrame example:

```python
import xlwings as xw
import pandas as pd

@xw.func
@xw.arg('x', pd.DataFrame)
def correl2(x):
    # x arrives as DataFrame
    return x.corr()
```

Import this function into Excel by clicking the import button of the xlwings add-in: For further details, see VBA: User Defined Functions (UDFs).
When reading/writing data to the active sheet, you don’t need a book object:

```python
>>> import xlwings as xw
>>> xw.Range('A1').value = 'something'
```

### 6.1 Python to Excel

The easiest way to connect to a book is offered by `xw.Book`: it looks for the book in all app instances and returns an error, should the same book be open in multiple instances. To connect to a book in the active app instance, use `xw.books` and to refer to a specific app, use:

```python
>>> app = xw.App()  # or something like xw.apps[0] for existing apps
>>> app.books['Book1']
```

<table>
<thead>
<tr>
<th></th>
<th><code>xw.Book</code></th>
<th><code>xw.books</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Unsaved book</td>
<td><code>xw.Book('Book1')</code></td>
<td><code>xw.books['Book1']</code></td>
</tr>
<tr>
<td>Book by (full)name</td>
<td><code>xw.Book(r'C:/path/to/file.xlsx')</code></td>
<td><code>xw.books.open(r'C:/path/to/file.xlsx')</code></td>
</tr>
</tbody>
</table>

**Note:** When specifying file paths on Windows, you should either use raw strings by putting an `r` in front of the string or use double backslashes like so: `C:\\path\\to\\file.xlsx`. 
6.2 Excel to Python (RunPython)

To reference the calling book when using RunPython in VBA, use \texttt{xw.Book.caller()}, see \textit{Call Python with “RunPython”}. Check out the section about \textit{Debugging} to see how you can call a script from both sides, Python and Excel, without the need to constantly change between \texttt{xw.Book.caller()} and one of the methods explained above.

6.3 User Defined Functions (UDFs)

Unlike RunPython, UDFs don’t need a call to \texttt{xw.Book.caller()}, see \textit{VBA: User Defined Functions (UDFs)}. However, it’s available (restricted to read-only though), which sometimes proofs to be useful.
The xlwings object model is very similar to the one used by VBA.

All code samples below depend on the following import:

```python
>>> import xlwings as xw
```

### 7.1 Active Objects

```python
# Active app (i.e. Excel instance)
>>> app = xw.apps.active

# Active book
>>> wb = xw.books.active  # in active app
>>> wb = app.books.active  # in specific app

# Active sheet
>>> sht = xw.sheets.active  # in active book
>>> sht = wb.sheets.active  # in specific book

# Range on active sheet
>>> xw.Range('A1')  # on active sheet of active book of active app
```

A Range can be instantiated with A1 notation, a tuple of Excel’s 1-based indices, a named range or two Range objects:

```python
xw.Range('A1')
xw.Range('A1:C3')
xw.Range((1,1))
```
7.2 Full qualification

Round brackets follow Excel’s behavior (i.e. 1-based indexing), while square brackets use Python’s 0-based indexing/slicing. As an example, the following expressions all reference the same range:

```
xw.apps[0].books[0].sheets[0].range('A1')
xw.apps(1).books(1).sheets(1).range('A1')
xw.apps[0].books['Book1'].sheets['Sheet1'].range('A1')
xw.apps(1).books('Book1').sheets('Sheet1').range('A1')
```

7.3 Range indexing/slicing

Range objects support indexing and slicing, a few examples:

```
>>> rng = xw.Book().sheets[0].range('A1:D5')
>>> rng[0, 0]
<Range [Workbook1]Sheet1!$A$1>
>>> rng[1]
<Range [Workbook1]Sheet1!$B$1>
>>> rng[:, 3:]
<Range [Workbook1]Sheet1!$D$1:$D$5>
>>> rng[1:3, 1:3]
<Range [Workbook1]Sheet1!$B$2:$C$3>
```

7.4 Range Shortcuts

Sheet objects offer a shortcut for range objects by using index/slice notation on the sheet object. This evaluates to either sheet.range or sheet.cells depending on whether you pass a string or indices/slices:

```
>>> sht = xw.Book().sheets['Sheet1']
>>> sht['A1']
<Range [Book1]Sheet1!$A$1>
>>> sht['A1:B5']
>>> sht[0, 1]
<Range [Book1]Sheet1!$B$1>
>>> sht[:10, :10]
<Range [Book1]Sheet1!$A$1:$J$10>
```
7.5 Object Hierarchy

The following shows an example of the object hierarchy, i.e. how to get from an app to a range object and all the way back:

```python
>>> rng = xw.app.books[0].sheets[0].range('A1')
>>> rng.sheet.book.app
<Excel App 1644>
```
This tutorial gives you a quick introduction to the most common use cases and default behaviour of xlwings when reading and writing values. For an in-depth documentation of how to control the behavior using the `options` method, have a look at *Converters and Options*.

All code samples below depend on the following import:

```python
>>> import xlwings as xw
```

### 8.1 Single Cells

Single cells are by default returned either as `float`, `unicode`, `None` or `datetime` objects, depending on whether the cell contains a number, a string, is empty or represents a date:

```python
>>> import datetime as dt
>>> sht = xw.Book().sheets[0]
>>> sht.range('A1').value = 1
>>> sht.range('A1').value
1.0
>>> sht.range('A2').value = 'Hello'
>>> sht.range('A2').value
'Hello'
>>> sht.range('A3').value is None
True
>>> sht.range('A4').value = dt.datetime(2000, 1, 1)
>>> sht.range('A4').value
datetime.datetime(2000, 1, 1, 0, 0)
```
8.2 Lists

- 1d lists: Ranges that represent rows or columns in Excel are returned as simple lists, which means that once they are in Python, you’ve lost the information about the orientation. If that is an issue, the next point shows you how to preserve this info:

```python
>>> sht = xw.Book().sheets[0]
>>> sht.range('A1').value = [[1], [2], [3], [4], [5]]  # Column orientation
    ↳ (nested list)
>>> sht.range('A1:A5').value
[1.0, 2.0, 3.0, 4.0, 5.0]
>>> sht.range('A1').value = [1, 2, 3, 4, 5]
>>> sht.range('A1:E1').value
[1.0, 2.0, 3.0, 4.0, 5.0]
```

To force a single cell to arrive as list, use:

```python
>>> sht.range('A1').options(ndim=1).value
[1.0]
```

**Note:** To write a list in column orientation to Excel, use `transpose`: `sht.range('A1').options(transpose=True).value = [1, 2, 3, 4]`

- 2d lists: If the row or column orientation has to be preserved, set `ndim` in the Range options. This will return the Ranges as nested lists (“2d lists”):

```python
>>> sht.range('A1:A5').options(ndim=2).value
[[1.0], [2.0], [3.0], [4.0], [5.0]]
>>> sht.range('A1:E1').options(ndim=2).value
[[1.0, 2.0, 3.0, 4.0, 5.0]]
```

- 2 dimensional Ranges are automatically returned as nested lists. When assigning (nested) lists to a Range in Excel, it’s enough to just specify the top left cell as target address. This sample also makes use of index notation to read the values back into Python:

```python
>>> sht.range('A10').value = [['Foo 1', 'Foo 2', 'Foo 3'], [10, 20, 30]]
>>> sht.range((10,1),(11,3)).value
[['Foo 1', 'Foo 2', 'Foo 3'], [10.0, 20.0, 30.0]]
```

**Note:** Try to minimize the number of interactions with Excel. It is always more efficient to do `sht.range('A1').value = [[1,2],[3,4]]` than `sht.range('A1').value = [1, 2]` and `sht.range('A2').value = [3, 4]`. 
8.3 Range expanding

You can get the dimensions of Excel Ranges dynamically through either the method `expand` or through the `expand` keyword in the `options` method. While `expand` gives back an expanded Range object, options are only evaluated when accessing the values of a Range. The difference is best explained with an example:

```python
>>> sht = xw.Book().sheets[0]
>>> sht.range('A1').value = [[1, 2], [3, 4]]
>>> rng1 = sht.range('A1').expand('table')  # or just .expand()
>>> rng2 = sht.range('A1').options(expand='table')
>>> rng1.value
[[1.0, 2.0], [3.0, 4.0]]
>>> rng2.value
[[1.0, 2.0], [3.0, 4.0]]
>>> sht.range('A3').value = [5, 6]
>>> rng1.value
[[1.0, 2.0], [3.0, 4.0]]
>>> rng2.value
[[1.0, 2.0], [3.0, 4.0], [5.0, 6.0]]
```

'table' expands to 'down' and 'right', the other available options which can be used for column or row only expansion, respectively.

Note: Using `expand()` together with a named Range as top left cell gives you a flexible setup in Excel: You can move around the table and change it’s size without having to adjust your code, e.g. by using something like `sht.range('NamedRange').expand().value`.

8.4 NumPy arrays

NumPy arrays work similar to nested lists. However, empty cells are represented by `nan` instead of `None`. If you want to read in a Range as array, set `convert=np.array` in the `options` method:

```python
>>> import numpy as np
>>> sht = xw.Book().sheets[0]
>>> sht.range('A1').value = np.eye(3)
>>> sht.range('A1').options(np.array, expand='table').value
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
```

8.5 Pandas DataFrames

```python
>>> sht = xw.Book().sheets[0]
>>> df = pd.DataFrame([[1.1, 2.2], [3.3, None]], columns=['one', 'two'])
>>> df
```
(continues on next page)
8.6 Pandas Series

```python
>>> import pandas as pd
>>> import numpy as np
>>> sht = xw.Book().sheets[0]
>>> s = pd.Series([1.1, 3.3, 5., np.nan, 6., 8.], name='myseries')
>>> s
0    1.1
1    3.3
2    5.0
3    NaN
4    6.0
5    8.0
Name: myseries, dtype: float64
>>> sht.range('A1').value = s
>>> sht.range('A1:B7').options(pd.Series).value
0    1.1
1    3.3
2    5.0
3    NaN
4    6.0
5    8.0
Name: myseries, dtype: float64
```

Note: You only need to specify the top left cell when writing a list, a NumPy array or a Pandas DataFrame to Excel, e.g.: `sht.range('A1').value = np.eye(10)`
Add-in

The xlwings add-in is the preferred way to be able to use RunPython or UDFs. Note that you don’t need an add-in if you just want to manipulate Excel from Python via xlwings.

**Note:** The ribbon of the add-in is compatible with Excel >= 2007 on Windows and >= 2016 on Mac. You could, however, use the add-in with earlier versions but you would need to change the settings directly in the config file, see below. On Mac, all UDF related functionality is not available.

**Note:** The add-in is password protected with the password xlwings. For debugging or to add new extensions, you need to unprotect it.

### 9.1 Installation

To install the add-in, it’s easiest to use the command line client: `xlwings addin install`. Technically, this copies the add-in from Python’s installation directory to Excel’s XLSTART folder. If you encounter issues, then you can also download the add-in (`xlwings.xlam`) from the GitHub Release
xlwings - Make Excel Fly!, Release dev

page (make sure you download the same version as the version of the Python package). Once downloaded, you can install the add-in by going to Developer > Excel Add-in > Browse. If you don’t see Developer as tab in your ribbon, make sure to activate the tab first under File > Options > Customize Ribbon (Mac: Cmd + , > Ribbon & Toolbar).

Then, to use RunPython or UDFs in a workbook, you need to set a reference to xlwings in the VBA editor, see screenshot (Windows: Tools > References..., Mac: it’s on the lower left corner of the VBA editor). Note that when you create a workbook via xlwings quickstart, the reference is already set.

![References - VBAProject](image)

### 9.2 Global Settings

While the defaults will often work out-of-the-box, you can change the global settings directly in the add-in:

- **Interpreter**: This is the path to the Python interpreter (works also with virtual or conda envs), e.g. "C:\Python35\pythonw.exe" or "/usr/local/bin/python3.5". An empty field defaults to pythonw that expects the interpreter to be set in the PATH on Windows or .bash_profile on Mac.

- **PYTHONPATH**: If the source file of your code is not found, add the path here.

- **UDF_MODULES**: Names of Python modules (without .py extension) from which the UDFs are being imported. Separate multiple modules by ";". Example: `UDF_MODULES = "common_udfs; myproject"` The default imports a file in the same directory as the Excel spreadsheet with the same name but ending in .py.

- **Debug UDFs**: Check this box if you want to run the xlwings COM server manually for debugging, see Debugging.

- **Log File**: Leave empty for default location (see below) or provide the full path, e.g. .

- **RunPython: Use UDF Server**: Uses the same COM Server for RunPython as for UDFs. This will be faster, as the interpreter doesn’t shut down after each call.

- **Restart UDF Server**: This shuts down the UDF Server/Python interpreter. It’ll be restarted upon the next function call.
9.3 Global Config: Ribbon/Config File

The settings in the xlwings Ribbon are stored in a config file that can also be manipulated externally. The location is:

- **Windows**: `.xlwings\xlwings.conf` in your user folder
- **Mac Excel 2016**: `~/Library/Containers/com.microsoft.Excel/Data/xlwings.conf`

# Mac Excel 2011: `~/xlwings/xlwings.conf`

The format is as follows (keys are uppercase):

```
"INTERPRETER","pythonw"
"PYTHONPATH",""
```

**Note:** Mac Excel 2011 users have to create and edit the config file manually under `~/xlwings/xlwings.conf` as the ribbon is not supported.

9.4 Workbook Directory Config: Config file

The global settings of the Ribbon/Config file can be overridden for one or more workbooks by creating a `xlwings.conf` file in the workbook’s directory.

9.5 Workbook Config: xlwings.conf Sheet

Workbook specific settings will override global (Ribbon) and workbook directory config files: Workbook specific settings are set by listing the config key/value pairs in a sheet with the name `xlwings.conf`. When you create a new project with `xlwings quickstart`, it’ll already have such a sheet but you need to rename it to `xlwings.conf` to make it active.

```

</tbody>
</table>
```

9.6 Alternative: Standalone VBA module

Sometimes it might be useful to run xlwings code without having to install an add-in first. To do so, you need to use the `standalone` option when creating a new project: `xlwings quickstart myproject --standalone`.
This will add the content of the add-in as a single VBA module so you don’t need to set a reference to the add-in anymore. It will still read in the settings from your `xlwings.conf` if you don’t override them by using a sheet with the name `xlwings.conf`.

### 9.7 Log File default locations

These log files are used for the error pop-up windows:

- **Windows**: `%APPDATA%\xlwings.log`
- **Mac with Excel 2011**: `/tmp/xlwings.log`
- **Mac with Excel 2016**: `~/Library/Containers/com.microsoft.Excel/Data/xlwings.log`
10.1 xlwings add-in

To get access to the RunPython function, you’ll need the xlwings addin (or VBA module), see Add-in.

For new projects, the easiest way to get started is by using the command line client with the quickstart command, see Command Line Client for details:

$ xlwings quickstart myproject

10.2 Call Python with “RunPython”

In the VBA Editor (Alt-F11), write the code below into a VBA module. xlwings quickstart automatically adds a new module with a sample call. If you rather want to start from scratch, you can add new module via Insert > Module.

```vba
Sub HelloWorld()
    RunPython ("import hello; hello.world()")
End Sub
```

This calls the following code in hello.py:

```python
# hello.py
import numpy as np
import xlwings as xw

def world():
    wb = xw.Book.caller()
    wb.sheets[0].range('A1').value = 'Hello World!'```
You can then attach `HelloWorld` to a button or run it directly in the VBA Editor by hitting F5.

**Note:** Place `xw.Book.caller()` within the function that is being called from Excel and not outside as a global variable. Otherwise it prevents Excel from shutting down properly upon exiting and leaves you with a zombie process when you use `OPTIMIZED_CONNECTION = True`.

### 10.3 Function Arguments and Return Values

While it’s technically possible to include arguments in the function call within `RunPython`, it’s not very convenient. Also, `RunPython` does not allow you to return values. To overcome these issues, use UDFs, see [VBA: User Defined Functions (UDFs)](VBA: User Defined Functions (UDFs)) - however, this is currently limited to Windows only.
This tutorial gets you quickly started on how to write User Defined Functions.

Note:

- UDFs are currently only available on Windows.
- For details of how to control the behaviour of the arguments and return values, have a look at Converters and Options.
- For a comprehensive overview of the available decorators and their options, check out the corresponding API docs: UDF decorators.

### 11.1 One-time Excel preparations

1) Enable Trust access to the VBA project object model under File > Options > Trust Center > Trust Center Settings > Macro Settings

2. Install the add-in via command prompt: `xlwings addin install` (see Add-in).

### 11.2 Workbook preparation

The easiest way to start a new project is to run `xlwings quickstart myproject` on a command prompt (see Command Line Client). This automatically adds the xlwings reference to the generated workbook.
11.3 A simple UDF

The default addin settings expect a Python source file in the way it is created by quickstart:

- in the same directory as the Excel file
- with the same name as the Excel file, but with a .py ending instead of .xlsm.

Alternatively, you can point to a specific module via UDF Modules in the xlwings ribbon.

Let’s assume you have a Workbook myproject.xlsm, then you would write the following code in myproject.py:

```python
import xlwings as xw

@xw.func
def double_sum(x, y):
    """Returns twice the sum of the two arguments""
    return 2 * (x + y)
```

- Now click on Import Python UDFs in the xlwings tab to pick up the changes made to myproject.py.
- Enter the formula =double_sum(1, 2) into a cell and you will see the correct result:

![Image of Excel cell with formula result]

- The docstring (in triple-quotes) will be shown as function description in Excel.

**Note:**

- You only need to re-import your functions if you change the function arguments or the function name.
- Code changes in the actual functions are picked up automatically (i.e. at the next calculation of the formula, e.g. triggered by Ctrl-Alt-F9), but changes in imported modules are not. This is the very behaviour of how Python imports work. If you want to make sure everything is in a fresh state, click Restart UDF Server.
- The `@xw.func` decorator is only used by xlwings when the function is being imported into Excel. It tells xlwings for which functions it should create a VBA wrapper function, otherwise it has no effect on how the functions behave in Python.

11.4 Array formulas: Get efficient

Calling one big array formula in Excel is much more efficient than calling many single-cell formulas, so it’s generally a good idea to use them, especially if you hit performance problems.
You can pass an Excel Range as a function argument, as opposed to a single cell and it will show up in Python as list of lists.

For example, you can write the following function to add 1 to every cell in a Range:

```python
@xw.func
def add_one(data):
    return [[cell + 1 for cell in row] for row in data]
```

To use this formula in Excel,

- Click on `Import Python UDFs` again
- Fill in the values in the range A1:B2
- Select the range D1:E2
- Type in the formula `=add_one(A1:B2)`
- Press Ctrl+Shift+Enter to create an array formula. If you did everything correctly, you’ll see the formula surrounded by curly braces as in this screenshot:

```
11.4.1 Number of array dimensions: ndim

The above formula has the issue that it expects a “two dimensional” input, e.g. a nested list of the form `[[1, 2], [3, 4]]`. Therefore, if you would apply the formula to a single cell, you would get the following error: `TypeError: 'float' object is not iterable`.

To force Excel to always give you a two-dimensional array, no matter whether the argument is a single cell, a column/row or a two-dimensional Range, you can extend the above formula like this:

```python
@xw.func
@xw.arg('data', ndim=2)
def add_one(data):
    return [[cell + 1 for cell in row] for row in data]
```

### 11.5 Array formulas with NumPy and Pandas

Often, you’ll want to use NumPy arrays or Pandas DataFrames in your UDF, as this unlocks the full power of Python’s ecosystem for scientific computing.

To define a formula for matrix multiplication using numpy arrays, you would define the following function:
import xlwings as xw
import numpy as np

@xw.func
@xw.arg('x', np.array, ndim=2)
@xw.arg('y', np.array, ndim=2)
def matrix_mult(x, y):
    return x @ y

Note: If you are not on Python >= 3.5 with NumPy >= 1.10, use x.dot(y) instead of x @ y.

A great example of how you can put Pandas at work is the creation of an array-based CORREL formula. Excel’s version of CORREL only works on 2 datasets and is cumbersome to use if you want to quickly get the correlation matrix of a few time-series, for example. Pandas makes the creation of an array-based CORREL2 formula basically a one-liner:

import xlwings as xw
import pandas as pd

@xw.func
@xw.arg('x', pd.DataFrame, index=False, header=False)
@xw.ret(index=False, header=False)
def CORREL2(x):
    """Like CORREL, but as array formula for more than 2 data sets""
    return x.corr()

11.6 @xw.arg and @xw.ret decorators

These decorators are to UDFs what the options method is to Range objects: they allow you to apply converters and their options to function arguments (@xw.arg) and to the return value (@xw.ret). For example, to convert the argument x into a pandas DataFrame and suppress the index when returning it, you would do the following:

@xw.func
@xw.arg('x', pd.DataFrame)
@xw.ret(index=False)
def myfunction(x):
    # x is a DataFrame, do something with it
    return x

For further details see the Converters and Options documentation.

11.7 Dynamic Array Formulas
Note: If your version of Excel supports the new native dynamic arrays, then you don’t have to do anything special, and you shouldn’t use the `expand` decorator! To check if your version of Excel supports it, see if you have the `=UNIQUE()` formula available. Native dynamic arrays were introduced in Office 365 Insider Fast at the end of September 2018.

As seen above, to use Excel’s array formulas, you need to specify their dimensions up front by selecting the result array first, then entering the formula and finally hitting `Ctrl-Shift-Enter`. In practice, it often turns out to be a cumbersome process, especially when working with dynamic arrays such as time series data. Since v0.10, xlwings offers dynamic UDF expansion:

This is a simple example that demonstrates the syntax and effect of UDF expansion:

```python
import numpy as np

@xw.func
@xw.ret(expand='table')
def dynamic_array(r, c):
    return np.random.randn(int(r), int(c))
```

Note:

- Expanding array formulas will overwrite cells without prompting
- Pre v0.15.0 doesn’t allow to have volatile functions as arguments, e.g. you cannot use functions like `=TODAY()` as arguments. Starting with v0.15.0, you can use volatile functions as input, but the UDF will be called more than 1x.
- Dynamic Arrays have been refactored with v0.15.0 to be proper legacy arrays: To edit a dynamic array with xlwings $\geq$ v0.15.0, you need to hit `Ctrl-Shift-Enter` while in the top left cell. Note that you don’t have to do that when you enter the formula for the first time.

11.7. Dynamic Array Formulas 35
11.8 Docstrings

The following sample shows how to include docstrings both for the function and for the arguments x and y that then show up in the function wizard in Excel:

```python
import xlwings as xw

@xw.func
def double_sum(x, y):
    """Returns twice the sum of the two arguments""
    return 2 * (x + y)
```

11.9 The “vba” keyword

It’s often helpful to get the address of the calling cell. Right now, one of the easiest ways to accomplish this is to use the vba keyword. vba, in fact, allows you to access any available VBA expression e.g. Application. Note, however, that currently you’re acting directly on the pywin32 COM object:

```python
@xw.func
def get_caller_address(xl_app):
    return xl_app.Caller.Address
```

11.10 Macros

On Windows, as alternative to calling macros via RunPython, you can also use the @xw.sub decorator:

```python
import xlwings as xw

def my_macro():
    """Writes the name of the Workbook into Range("A1") of Sheet 1""
    wb = xw.Book.caller()
    wb.sheets[0].range('A1').value = wb.name
```

After clicking on Import Python UDFs, you can then use this macro by executing it via Alt + F8 or by binding it e.g. to a button. To the latter, make sure you have the Developer tab selected under File > Options > Customize Ribbon. Then, under the Developer tab, you can insert a button via Insert > Form Controls. After drawing the button, you will be prompted to assign a macro to it and you can select my_macro.
11.11 Call UDFs from VBA

Imported functions can also be used from VBA. For example, for a function returning a 2d array:

```vba
Sub MySub()
    Dim arr() As Variant
    Dim i As Long, j As Long

    arr = my_imported_function(...)  
    For j = LBound(arr, 2) To UBound(arr, 2)
        For i = LBound(arr, 1) To UBound(arr, 1)
            Debug.Print "(" & i & "," & j & ")", arr(i, j)
        Next i
        Next j
End Sub
```

11.12 Asynchronous UDFs

New in version v0.14.0.

xlwings offers an easy way to write asynchronous functions in Excel. Asynchronous functions return immediately with #N/A waiting.... While the function is waiting for its return value, you can use Excel to do other stuff and whenever the return value is available, the cell value will be updated.

The only available mode is currently async_mode='threading', meaning that it’s useful for I/O-bound tasks, for example when you fetch data from an API over the web.

You make a function asynchronous simply by giving it the respective argument in the function decorator. In this example, the time consuming I/O-bound task is simulated by using `time.sleep`:

```python
import xlwings as xw
import time

@xw.func(async_mode='threading')
def myfunction(a):
    time.sleep(5)  # long running tasks
    return a
```

You can use this function like any other xlwings function, simply by putting `=myfunction("abcd")` into a cell (after you have imported the function, off course).

Note that xlwings doesn’t use the native asynchronous functions that were introduced with Excel 2010, so xlwings asynchronous functions are supported with any version of Excel.
Since xlwings runs in every Python environment, you can use your preferred way of debugging.

- **RunPython**: When calling Python through `RunPython`, you can set a mock_caller to make it easy to switch back and forth between calling the function from Excel and Python.

- **UDFs**: For debugging User Defined Functions, xlwings offers a convenient debugging server

To begin with, Excel will show Python errors in a Message Box:

![Error Message](image)

**Note:** On Mac, if the `import` of a module/package fails before xlwings is imported, the popup will not be shown and the StatusBar will not be reset. However, the error will still be logged in the log file. For the location of the logfile, see *Log File default locations.*
12.1 RunPython

Consider the following sample code of your Python source code my_module.py:

```python
# my_module.py
import os
import xlwings as xw

def my_macro():
    wb = xw.Book.caller()
    wb.sheets[0].range('A1').value = 1

if __name__ == '__main__':
    # Expects the Excel file next to this source file, adjust accordingly.
    xw.Book('myfile.xlsm').set_mock_caller()
    my_macro()
```

my_macro() can now easily be run from Python for debugging and from Excel via RunPython without having to change the source code:

```vbnet
Sub my_macro()
    RunPython ("import my_module; my_module.my_macro()")
End Sub
```

12.2 UDF debug server

Windows only: To debug UDFs, just check the Debug UDFs in the Add-in, at the top of the xlwings VBA module. Then add the following lines at the end of your Python source file and run it. Depending on which IDE you use, you might need to run the code in “debug” mode (e.g. in case you’re using PyCharm or PyDev):

```python
if __name__ == '__main__':
    xw.serve()
```

When you recalculate the Sheet (Ctrl-Alt-F9), the code will stop at breakpoints or output any print calls that you may have.

The following screenshot shows the code stopped at a breakpoint in the community version of PyCharm:

---

**Note:** When running the debug server from a command prompt, there is currently no gracious way to terminate it, but closing the command prompt will kill it.
12.2. UDF debug server
Using `pictures.add()` it is easy to paste a Matplotlib plot as picture in Excel.

## 13.1 Getting started

The easiest sample boils down to:

```python
>>> import matplotlib.pyplot as plt
>>> import xlwings as xw

>>> fig = plt.figure()
>>> plt.plot([1, 2, 3])

>>> sht = xw.Book().sheets[0]
>>> sht.pictures.add(fig, name='MyPlot', update=True)
```

**Note:** If you set `update=True`, you can resize and position the plot on Excel: subsequent calls to `pictures.add()` with the same name (`'MyPlot'`) will update the picture without changing its position or size.

## 13.2 Full integration with Excel

Calling the above code with `RunPython` and binding it e.g. to a button is straightforward and works cross-platform.
However, on Windows you can make things feel even more integrated by setting up a UDF along the following lines:

```python
@xw.func
def myplot(n):
    sht = xw.Book().caller().sheets.active
    fig = plt.figure()
    plt.plot(range(int(n)))
    sht.pictures.add(fig, name='MyPlot', update=True)
    return 'Plotted with n={}'.format(n)
```

If you import this function and call it from cell B2, then the plot gets automatically updated when cell B1 changes:

### 13.3 Properties

Size, position and other properties can either be set as arguments within `pictures.add()`, or by manipulating the picture object that is returned, see `xlwings.Picture()`.

For example:

```python
>>> sht = xw.Book().sheets[0]
>>> sht.pictures.add(fig, name='MyPlot', update=True,
                     left=sht.range('B5').left, top=sht.range('B5').top)
```

or:

```python
>>> plot = sht.pictures.add(fig, name='MyPlot', update=True)
>>> plot.height /= 2
>>> plot.width /= 2
```
Plot with \( n = 5.0 \)
13.4 Getting a Matplotlib figure

Here are a few examples of how you get a matplotlib figure object:

- via PyPlot interface:

  ```python
  import matplotlib.pyplot as plt
  fig = plt.figure()
  plt.plot([1, 2, 3, 4, 5])
  ```

  or:

  ```python
  import matplotlib.pyplot as plt
  plt.plot([1, 2, 3, 4, 5])
  fig = plt.gcf()
  ```

- via object oriented interface:

  ```python
  from matplotlib.figure import Figure
  fig = Figure(figsize=(8, 6))
  ax = fig.add_subplot(111)
  ax.plot([1, 2, 3, 4, 5])
  ```

- via Pandas:

  ```python
  import pandas as pd
  import numpy as np
  
  df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
  ax = df.plot(kind='bar')
  fig = ax.get_figure()
  ```
Conversors and Options

Introduced with v0.7.0, converters define how Excel ranges and their values are converted both during reading and writing operations. They also provide a consistent experience across xlwings.Range objects and User Defined Functions (UDFs).

Converters are explicitly set in the options method when manipulating Range objects or in the @xw.arg and @xw.ret decorators when using UDFs. If no converter is specified, the default converter is applied when reading. When writing, xlwings will automatically apply the correct converter (if available) according to the object’s type that is being written to Excel. If no converter is found for that type, it falls back to the default converter.

All code samples below depend on the following import:

```python
>>> import xlwings as xw
```

Syntax:

```
xw.Range.reading
  xw.Range.options(convert=convert, **kwargs).value

xw.Range.writing
  xw.Range.options(convert=convert, **kwargs).value = myvalue

UDFs

@arg('x', convert=convert, **kwargs)
@ret(convert=convert, **kwargs)
```

Note: Keyword arguments (kwargs) may refer to the specific converter or the default converter. For example, to set the numbers option in the default converter and the index option in the DataFrame converter, you would write:
14.1 Default Converter

If no options are set, the following conversions are performed:

- single cells are read in as floats in case the Excel cell holds a number, as unicode in case it holds text, as datetime if it contains a date and as None in case it is empty.
- columns/rows are read in as lists, e.g. [None, 1.0, 'a string']
- 2d cell ranges are read in as list of lists, e.g. [[None, 1.0, 'a string'], [None, 2.0, 'another string']]

The following options can be set:

- **ndim**
  Force the value to have either 1 or 2 dimensions regardless of the shape of the range:

  ```python
  >>> import xlwings as xw
  >>> sht = xw.Book().sheets[0]
  >>> sht.range('A1').value = [[1, 2], [3, 4]]
  >>> sht.range('A1').value
  1.0
  >>> sht.range('A1').options(ndim=1).value
  [1.0]
  >>> sht.range('A1').options(ndim=2).value
  [[1.0]]
  >>> sht.range('A1:A2').value
  [1.0 3.0]
  >>> sht.range('A1:A2').options(ndim=2).value
  [[1.0], [3.0]]
  ```

- **numbers**
  By default cells with numbers are read as float, but you can change it to int:

  ```python
  >>> sht.range('A1').value = 1
  >>> sht.range('A1').value
  1.0
  >>> sht.range('A1').options(numbers=int).value
  1
  ```

  Alternatively, you can specify any other function or type which takes a single float argument.
  Using this on UDFs looks like this:

  ```python
  @xw.func
  @xw.arg('x', numbers=int)
  def myfunction(x):
  ```
# all numbers in x arrive as int
return x

Note: Excel always stores numbers internally as floats, which is the reason why the int converter rounds numbers first before turning them into integers. Otherwise it could happen that e.g. 5 might be returned as 4 in case it is represented as a floating point number that is slightly smaller than 5. Should you require Python’s original int in your converter, use raw int instead.

• dates

By default cells with dates are read as datetime.datetime, but you can change it to datetime.date:

- Range:

```python
>>> import datetime as dt
>>> sht.range('A1').options(dates=dt.date).value
```

- UDFs: `@xw.arg('x', dates=dt.date)

Alternatively, you can specify any other function or type which takes the same keyword arguments as datetime.datetime, for example:

```python
>>> my_date_handler = lambda year, month, day, **kwargs: "%04i-%02i-%02i" % (year, month, day)
>>> sht.range('A1').options(dates=my_date_handler).value
'2017-02-20'
```

• empty

Empty cells are converted per default into None, you can change this as follows:

- Range: `>>> sht.range('A1').options(empty='NA').value`

- UDFs: `@xw.arg('x', empty='NA')`

• transpose

This works for reading and writing and allows us to e.g. write a list in column orientation to Excel:

- Range: `sht.range('A1').options(transpose=True).value = [1, 2, 3]`

- UDFs:

```python
@xw.arg('x', transpose=True)
@xw.ret(transpose=True)
def myfunction(x):
   # x will be returned unchanged as transposed both when reading and writing
   return x
```

• expand

This works the same as the Range properties `table, vertical` and `horizontal` but is only evaluated when getting the values of a Range:
Note: The `expand` method is only available on `Range` objects as UDFs only allow to manipulate the calling cells.

### 14.2 Built-in Converters

xlwings offers several built-in converters that perform type conversion to **dictionaries**, **NumPy arrays**, **Pandas Series** and **DataFrames**. These build on top of the default converter, so in most cases the options described above can be used in this context, too (unless they are meaningless, for example the `ndim` in the case of a dictionary).

It is also possible to write and register custom converter for additional types, see below.

The samples below can be used with both `xlwings.Range` objects and UDFs even though only one version may be shown.

#### 14.2.1 Dictionary converter

The dictionary converter turns two Excel columns into a dictionary. If the data is in row orientation, use `transpose`:

```python
>>> sht = xw.sheets.active
>>> sht.range('A1:B2').options(dict).value
({'a': 1.0, 'b': 2.0})
```
14.2.2 Numpy array converter

**options:** dtype=None, copy=True, order=None, ndim=None

The first 3 options behave the same as when using np.array() directly. Also, ndim works the same as shown above for lists (under default converter) and hence returns either numpy scalars, 1d arrays or 2d arrays.

**Example:**

```python
>>> import numpy as np
>>> sht = xw.Book().sheets[0]
>>> sht.range('A1').options(transpose=True).value = np.array([1, 2, 3])
>>> sht.range('A1:A3').options(np.array, ndim=2).value
array([[ 1.],
       [ 2.],
       [ 3.]]))
```

14.2.3 Pandas Series converter

**options:** dtype=None, copy=False, index=1, header=True

The first 2 options behave the same as when using pd.Series() directly. ndim doesn’t have an effect on Pandas series as they are always expected and returned in column orientation.

**index:** int or Boolean

When reading, it expects the number of index columns shown in Excel.
When writing, include or exclude the index by setting it to True or False.

**header:** Boolean

When reading, set it to False if Excel doesn’t show either index or series names.
When writing, include or exclude the index and series names by setting it to True or False.

For index and header, 1 and True may be used interchangeably.

**Example:**

```python
>>> sht = xw.Book().sheets[0]
>>> s = sht.range('A1').options(pd.Series, expand='table').value
>>> s
date
2001-01-01  1
2001-01-02  2

```
xlwings - Make Excel Fly!, Release dev

2001-01-05  5
2001-01-06  6
Name: series name, dtype: float64
>>> sht.range('D1', header=False).value = s

14.2.4 Pandas DataFrame converter

**options:** dtype=None, copy=False, index=1, header=1

The first 2 options behave the same as when using `pd.DataFrame()` directly. `ndim` doesn’t have an effect on Pandas DataFrames as they are automatically read in with `ndim=2`.

**index:** int or Boolean

- When reading, it expects the number of index columns shown in Excel.
- When writing, include or exclude the index by setting it to True or False.

**header:** int or Boolean

- When reading, it expects the number of column headers shown in Excel.
- When writing, include or exclude the index and series names by setting it to True or False.

For index and header, 1 and True may be used interchangeably.

**Example:**

```python
>>> sht = xw.Book().sheets[0]
>>> df = sht.range('A1:D5').options(pd.DataFrame, header=2).value
>>> df
   a  b
  c  d  e
ix
10 1  2  3
20 4  5  6
30 7  8  9
# Writing back using the defaults:
>>> sht.range('A1').value = df
```

(continues on next page)
# Writing back and changing some of the options, e.g. getting rid of the index:

```python
>>> sht.range('B7').options(index=False).value = df
```

The same sample for UDF (starting in `Range('A13')` on screenshot) looks like this:

```python
@xw.func
@xw.arg('x', pd.DataFrame, header=2)
@xw.ret(index=False)
def myfunction(x):
    # x is a DataFrame, do something with it
    return x
```

## 14.2.5 xw.Range and ‘raw’ converters

Technically speaking, these are “no-converters”.

- If you need access to the `xlwings.Range` object directly, you can do:

  ```python
  @xw.func
  @xw.arg('x', xw.Range)
def myfunction(x):
      return x.formula
  ```

  This returns `x` as `xlwings.Range` object, i.e. without applying any converters or options.

- The raw converter delivers the values unchanged from the underlying libraries (`pywin32` on Windows and `appscript` on Mac), i.e. no sanitizing/cross-platform harmonizing of values are being made. This might be useful in a few cases for efficiency reasons. E.g:
14.3 Custom Converter

Here are the steps to implement your own converter:

- Inherit from `xlwings.conversion.Converter`
- Implement both a `read_value` and `write_value` method as static- or classmethod:
  - In `read_value`, `value` is what the base converter returns: hence, if no `base` has been specified it arrives in the format of the default converter.
  - In `write_value`, `value` is the original object being written to Excel. It must be returned in the format that the base converter expects. Again, if no `base` has been specified, this is the default converter.

The `options` dictionary will contain all keyword arguments specified in the `xw.Range.options` method, e.g. when calling `xw.Range('A1').options(myoption='some value')` or as specified in the `@arg` and `@ret` decorator when using UDFs. Here is the basic structure:

```python
from xlwings.conversion import Converter

class MyConverter(Converter):
    @staticmethod
    def read_value(value, options):
        myoption = options.get('myoption', default_value)
        return_value = value  # Implement your conversion here
        return return_value

    @staticmethod
    def write_value(value, options):
        myoption = options.get('myoption', default_value)
        return_value = value  # Implement your conversion here
        return return_value
```

- Optional: set a `base` converter (`base` expects a class name) to build on top of an existing converter, e.g. for the built-in ones: `DictConverter, NumpyArrayConverter, PandasDataFrameConverter, PandasSeriesConverter`
- Optional: register the converter: you can (a) register a type so that your converter becomes the default for this type during write operations and/or (b) you can register an alias that will allow you to explicitly call your converter by name instead of just by class name
The following examples should make it much easier to follow - it defines a DataFrame converter that extends the built-in DataFrame converter to add support for dropping nan’s:

```python
from xlwings.conversion import Converter, PandasDataFrameConverter

class DataFrameDropna(Converter):
    base = PandasDataFrameConverter

    @staticmethod
    def read_value(builtin_df, options):
        dropna = options.get('dropna', False)  # set default to False
        if dropna:
            converted_df = builtin_df.dropna()
        else:
            converted_df = builtin_df
        # This will arrive in Python when using the DataFrameDropna converter for reading
        return converted_df

    @staticmethod
    def write_value(df, options):
        dropna = options.get('dropna', False)
        if dropna:
            converted_df = df.dropna()
        else:
            converted_df = df
        # This will be passed to the built-in PandasDataFrameConverter when writing
        return converted_df
```

Now let’s see how the different converters can be applied:

```python
# Fire up a Workbook and create a sample DataFrame
sht = xw.Book().sheets[0]
df = pd.DataFrame([[[1.,10.],[2.,np.nan]], [3., 30.]]

# Default converter for DataFrames:
# Write
sht.range('A1').value = df
# Read
sht.range('A1:C4').options(pd.DataFrame).value

# DataFrameDropna converter:
# Write
sht.range('A7').options(DataFrameDropna, dropna=True).value = df
# Read
sht.range('A1:C4').options(DataFrameDropna, dropna=True).value
```

14.3. Custom Converter 55
• Register an alias (optional):

```python
DataFrameDropna.register('df_dropna')

# Write
sht.range('A12').options('df_dropna', dropna=True).value = df

# Read
sht.range('A1:C4').options('df_dropna', dropna=True).value
```

• Register DataFrameDropna as default converter for DataFrames (optional):

```python
DataFrameDropna.register(pd.DataFrame)

# Write
sht.range('A13').options(dropna=True).value = df

# Read
sht.range('A1:C4').options(pd.DataFrame, dropna=True).value
```

These samples all work the same with UDFs, e.g.:

```python
@xw.func
@arg('x', DataFrameDropna, dropna=True)
@ret(DataFrameDropna, dropna=True)
def myfunction(x):
    # ...
    return x
```

**Note:** Python objects run through multiple stages of a transformation pipeline when they are being written to Excel. The same holds true in the other direction, when Excel/COM objects are being read into Python.

Pipelines are internally defined by `Accessor` classes. A Converter is just a special Accessor which converts to/from a particular type by adding an extra stage to the pipeline of the default Accessor. For example, the `PandasDataFrameConverter` defines how a list of list (as delivered by the default Accessor) should be turned into a Pandas DataFrame.

The `Converter` class provides basic scaffolding to make the task of writing a new Converter easier. If you need more control you can subclass `Accessor` directly, but this part requires more work and is currently undocumented.
New in version 0.13.0.

While xlwings is not technically thread safe, it’s still easy to use it in threads as long as you have at least v0.13.0 and stick to a simple rule: Do not pass xlwings objects to threads. This rule isn’t a requirement on macOS, but it’s still recommended if you want your programs to be cross-platform.

Consider the following example that will NOT work:

```python
import threading
from queue import Queue
import xlwings as xw

num_threads = 4

def write_to_workbook():
    while True:
        rng = q.get()
        rng.value = rng.address
        print(rng.address)
        q.task_done()

q = Queue()

for i in range(num_threads):
    t = threading.Thread(target=write_to_workbook)
    t.daemon = True
    t.start()

```

(continues on next page)
# THIS DOESN'T WORK - passing xlwings objects to threads will fail!
rng = xw.Book('Book1.xlsx').sheets[0].range(cell)
q.put(rng)
q.join()

To make it work, you simply have to fully qualify the cell reference in the thread instead of passing a `Book` object:

```python
import threading
from queue import Queue
import xlwings as xw

num_threads = 4

def write_to_workbook():
    while True:
        cell_ = q.get()
        xw.Book('Book1.xlsx').sheets[0].range(cell_).value = cell_
        print(address)
        q.task_done()

q = Queue()
for i in range(num_threads):
    t = threading.Thread(target=write_to_workbook)
    t.daemon = True
    t.start()
    q.put(cell)
q.join()
```
xlwings comes with a command line client that makes it easy to set up workbooks and install the add-in. On Windows, type the commands into a Command Prompt, on Mac, type them into a Terminal.

## 16.1 Quickstart

- `xlwings quickstart myproject`

This command is by far the fastest way to get off the ground: It creates a new folder `myproject` with an Excel workbook that already has the reference to the xlwings addin and a Python file, ready to be used right away:

```plaintext
myproject
    |--myproject.xlsm
    |--myproject.py
```

If you want to use xlwings via VBA module instead of addin, use the `--standalone` or `-s` flag:

`xlwings quickstart myproject --standalone`

## 16.2 Add-in

The `addin` command makes it easy on Windows to install/remove the addin. On Mac, you need to install it manually, but `xlwings addin install` will show you how to do it.

**Note:** Excel needs to be closed before installing/updating the add-in via command line. If you’re still getting an error, start the Task Manager and make sure there are no `EXCEL.EXE` processes left.
• `xlwings addin install`: Copies the xlwings add-in to the XLSTART folder
• `xlwings addin update`: Replaces the current add-in with the latest one
• `xlwings addin remove`: Removes the add-in from the XLSTART folder
• `xlwings addin status`: Shows if the add-in is installed together with the installation path

After installing the add-in, it will be available as xlwings tab on the Excel Ribbon.

New in version 0.6.0.

### 16.3 RunPython

Only required if you are on Mac, are using Excel 2016 and have xlwings installed via conda or as part of Anaconda. To enable the RunPython calls in VBA, run this one time:

```
xlwings runpython install
```

Alternatively, install xlwings with pip.

New in version 0.7.0.
CHAPTER 17

Missing Features

If you’re missing a feature in xlwings, do the following:

1. Most importantly, open an issue on GitHub. If it’s something bigger or if you want support from other users, consider opening a feature request. Adding functionality should be user driven, so only if you tell us about what you’re missing, it’s eventually going to find its way into the library. By the way, we also appreciate pull requests!

2. Workaround: in essence, xlwings is just a smart wrapper around pywin32 on Windows and appscript on Mac. You can access the underlying objects by calling the api property:

```python
>>> sht = xw.Book().sheets[0]
>>> sht.api
<COMObject <unknown>> # Windows/pywin32
app(pid=2319).workbooks['Workbook1'].worksheets[1] # Mac/appscript
```

This works accordingly for the other objects like `sht.range('A1').api` etc.

The underlying objects will offer you pretty much everything you can do with VBA, using the syntax of pywin32 (which pretty much feels like VBA) and appscript (which doesn’t feel like VBA). But apart from looking ugly, keep in mind that it makes your code platform specific (!), i.e. even if you go for option 2), you should still follow option 1) and open an issue so the feature finds it’s way into the library (cross-platform and with a Pythonic syntax).

17.1 Example: Workaround to use VBA’s `Range.WrapText`

```python
# Windows
sht.range('A1').api.WrapText = True
```

(continues on next page)
# Mac
sht.range('A1').api.wrap_text.set(True)
xlwings can also be used to call Python functions from VBA within Office apps other than Excel (like Outlook, Access etc.).

**Note:** New in v0.12.0 and still in a somewhat early stage that involves a bit of manual work. Currently, this functionality is only available on Windows for UDFs. The RunPython functionality is currently not supported.

### 18.1 How To

1. As usual, write your Python function and import it into Excel (see *VBA: User Defined Functions (UDFs)*).

2. Press Alt-F11 to get into the VBA editor, then right-click on the xlwings_udfs VBA module and select Export File... Save the xlwings_udfs.bas file somewhere.

3. Switch into the other Office app, e.g. Microsoft Access and click again Alt-F11 to get into the VBA editor. Right-click on the VBA Project and Import File..., then select the file that you exported in the previous step. Once imported, replace the app name in the first line to the one that you are using, i.e. Microsoft Access or Microsoft Outlook etc. so that the first line then reads: #Const App = "Microsoft Access"

4. Now import the standalone xlwings VBA module (xlwings.bas). You can find it in your xlwings installation folder. To know where that is, do:

```python
>>> import xlwings as xw
>>> xwings.__path__
```
And finally do the same as in the previous step and replace the App name in the first line with the name of the corresponding app that you are using. You are now able to call the Python function from VBA.

18.2 Config

The other Office apps will use the same global config file as you are editing via the Excel ribbon add-in. When it makes sense, you’ll be able to use the directory config file (e.g. you can put it next to your Access or Word file) or you can hardcode the path to the config file in the VBA standalone module, e.g. in the function GetDirectoryConfigFilePath (e.g. suggested when using Outlook that doesn’t really have the same concept of files like the other Office apps). NOTE: For Office apps without file concept, you need to make sure that the PYTHONPATH points to the directory with the Python source file. For details on the different config options, see Config.
 CHAPTER 19  

xlwings with R and Julia  

While xlwings is a pure Python package, there are cross-language packages that allow for a relative straightforward use from/with other languages. This means, however, that you’ll always need to have Python with xlwings installed in addition to R or Julia. We recommend the Anaconda distribution, see also Installation.

19.1 R

The R instructions are for Windows, but things work accordingly on Mac except that calling the R functions as User Defined Functions is not supported at the moment (but RunPython works, see Call Python with “RunPython”).

Setup:

- Install R and Python
- Add R_HOME environment variable to base directory of installation, e.g. C:\Program Files\R\R-x.x.x
- Add R_USER environment variable to user folder, e.g. C:\Users\<user>
- Add C:\Program Files\R\R-x.x.x\bin to PATH
- Restart Windows because of the environment variables (!)

19.1.1 Simple functions with R

Original R function that we want to access from Excel (saved in r_file.R):
myfunction <- function(x, y){
    return(x * y)
}

Python wrapper code:

```python
import xlwings as xw
import rpy2.robjects as robjects
# you might want to use some relative path or place the file in R's current working dir
robjects.r.source(r"C:\path\to\r_file.R")

@xw.func
def myfunction(x, y):
    myfunc = robjects.r['myfunction']
    return tuple(myfunc(x, y))
```

After importing this function (see: VBA: User Defined Functions (UDFs)), it will be available as UDF from Excel.

### 19.1.2 Array functions with R

Original R function that we want to access from Excel (saved in r_file.R):

```r
array_function <- function(m1, m2){
    # Matrix multiplication
    return(m1 %*% m2)
}
```

Python wrapper code:

```python
import xlwings as xw
import numpy as np
import rpy2.robjects as robjects
from rpy2.robjects import numpy2ri

robjects.r.source(r"C:\path\to\r_file.R")
numpy2ri.activate()

@xw.func
@xw.arg("x", np.array, ndim=2)
@xw.arg("y", np.array, ndim=2)
def array_function(x, y):
    array_func = robjects.r['array_function']
    return np.array(array_func(x, y))
```

After importing this function (see: VBA: User Defined Functions (UDFs)), it will be available as UDF from Excel.
19.2 Julia

Setup:

- Install Julia and Python
- Run `Pkg.add("PyCall")` from an interactive Julia interpreter

xlwings can then be called from Julia with the following syntax (the colons take care of automatic type conversion):

```
julia> using PyCall
julia> @pyimport xlwings as xw

julia> xw.Book()
PyObject <Book [Workbook1]>

julia> xw.Range("A1":[value] = "Hello World"
julia> xw.Range("A1":[value]
"Hello World"
```
It’s easy to extend the xlwings add-in with own code like UDFs or RunPython macros, so that they can be deployed without end users having to import or write the functions themselves. Just add another VBA module to the xlwings addin with the respective code.

UDF extensions can be used from every workbook without having to set a reference.

### 20.1 In-Excel SQL

The xlwings addin comes with a built-in extension that adds in-Excel SQL syntax (sqlite dialect):

```
=sql(SQL Statement, table a, table b, ...)
```
As this extension uses UDFs, it’s only available on Windows right now.
21.1 Issue: dll not found

Solution:

1. xlwings32-<version>.dll and xlwings64-<version>.dll are both in the same directory as your python.exe. If not, something went wrong with your installation. Reinstall it with pip or conda, see Installation.

2. Check your Interpreter in the add-in or config sheet. If it is empty, then you need to be able to open a windows command prompt and type python to start an interactive Python session. If you get the error 'python' is not recognized as an internal or external command, operable program or batch file, then you have two options: Either add the path of where your python.exe lives to your Windows path (see https://www.computerhope.com/issues/ch000549.htm) or set the full path to your interpreter in the add-in or your config sheet, e.g. C:\Users\MyUser\anaconda\pythonw.exe
New in version 0.13.0.

## 22.1 Quickstart

xlwings offers an easy way to expose an Excel workbook via REST API both on Windows and macOS. This can be useful when you have a workbook running on a single computer and want to access it from another computer. Or you can build a Linux based web app that can interact with a legacy Excel application while you are in the progress of migrating the Excel functionality into your web app (if you need help with that, give us a shout).

You can run the REST API server from a command prompt or terminal as follows (this requires Flask>=1.0, so make sure to pip install Flask):

```bash
xlwings restapi run
```

Then perform a GET request e.g. via PowerShell on Windows or Terminal on Mac (while having an unsaved “Book1” open). Note that you need to run the server and the GET request from two separate terminals (or you can use something more convenient like Postman or Insomnia for testing the API):

```bash
{
  "address": "$A$1:$B$2",
  "color": null,
  "column": 1,
  "column_width": 10.0,
  "count": 4,
  "current_region": "$A$1:$B$2",
  "formula": [
```

(continues on next page)
In the command prompt where your server is running, press Ctrl-C to shut it down again.

The xlwings REST API is a thin wrapper around the Python API which makes it very easy if you have worked previously with xlwings. It also means that the REST API does require the Excel application to be up and running which makes it a great choice if the data in your Excel workbook is constantly changing as the REST API will always deliver the current state of the workbook without the need of saving it first.

Note: Currently, we only provide the GET methods to read the workbook. If you are also interested in the POST methods to edit the workbook, let us know via GitHub issues. Some other things will also need improvement, most notably exception handling.
22.2 Run the server

`xlwings restapi run` will run a Flask development server on `http://127.0.0.1:5000`. You can provide `--host` and `--port` as command line args and it also respects the Flask environment variables like `FLASK_ENV=development`.

If you want to have more control, you can run the server directly with Flask, see the Flask docs for more details:

```
set FLASK_APP=xlwings.rest.api
flask run
```

If you are on Mac, use `export FLASK_APP=xlwings.rest.api` instead of `set FLASK_APP=xlwings.rest.api`.

For production, you can use any WSGI HTTP Server like `gunicorn` (on Mac) or `waitress` (on Mac/Windows) to serve the API. For example, with `gunicorn` you would do: `gunicorn xlwings.rest.api:api`. Or with `waitress` (adjust the host accordingly if you want to make the api accessible from outside of localhost):

```
from xlwings.rest.api import api
from waitress import serve
serve(wsgiapp, host='127.0.0.1', port=5000)
```

22.3 Indexing

While the Python API offers Python’s 0-based indexing (e.g. `xw.books[0]`) as well as Excel’s 1-based indexing (e.g. `xw.books(1)`), the REST API only offers 0-based indexing, e.g. `/books/0`.

22.4 Range Options

The REST API accepts Range options as query parameters, see `xlwings.Range.options()` e.g. `/book/book1/sheets/0/range/A1?expand=table&transpose=true`

Remember that options only affect the value property.

22.5 Endpoint overview

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Corresponds to</th>
<th>Short Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/book</td>
<td>Book</td>
<td>Finds your workbook across all open instances of Excel and will open it if it can’t find it</td>
</tr>
<tr>
<td>/books</td>
<td>Books</td>
<td>Books collection of the active Excel instance</td>
</tr>
<tr>
<td>/apps</td>
<td>Apps</td>
<td>This allows you to specify the Excel instance you want to work with</td>
</tr>
</tbody>
</table>
## 22.6 Endpoint details

### 22.6.1 /book

**GET /book/**<fullname_or_name>**/**

Example response:

```json
{
    "app": 1104,
    "fullname": "C:\Users\felix\DEV\xlwings\scripts\Book1.xlsx",
    "name": "Book1.xlsx",
    "names": [
        "Sheet1!myname1",
        "myname2"
    ],
    "selection": "Sheet2!$A$1",
    "sheets": [
        "Sheet1",
        "Sheet2"
    ]
}
```

**GET /book/**<fullname_or_name>**/names**

Example response:

```json
{
    "names": [
        {
            "name": "Sheet1!myname1",
            "refers_to": "=Sheet1!$B$2:$C$3"
        },
        {
            "name": "myname2",
            "refers_to": "=Sheet1!$A$1"
        }
    ]
}
```

**GET /book/**<fullname_or_name>**/names/**<name>**

Example response:

```json
{
    "name": "myname2",
    "refers_to": "=Sheet1!$A$1"
}
```

**GET /book/**<fullname_or_name>**/names/**<name>**/range**

Example response:
GET /book/<fullname_or_name>/sheets

Example response:

```json
{
  "sheets": [
    {
      "charts": [
        "Chart 1"
      ],
      "name": "Sheet1",
      "names": [
        "Sheet1!myname1"
      ],
      "pictures": [
        "Picture 3"
      ],
      "shapes": [
        "Chart 1",
        "Picture 3"
      ],
      "used_range": "$A$1:$B$2"
    },
    {
      "charts": [],
      "name": "Sheet2",
      "names": []
    }
  ]
}
```
GET /book/<fullname_or_name>/sheets/<sheet_name_or_ix>

Example response:

{
    "charts": [ 
        "Chart 1"
    ],
    "name": "Sheet1",
    "names": [ 
        "Sheet1!mynamel"
    ],
    "pictures": [ 
        "Picture 3"
    ],
    "shapes": [ 
        "Chart 1",
        "Picture 3"
    ],
    "used_range": "$A$1:$B$2"
}

GET /book/<fullname_or_name>/sheets/<sheet_name_or_ix>/charts

Example response:

{
    "charts": [ 
        { 
            "chart_type": "line",
            "height": 211.0,
            "left": 0.0,
            "name": "Chart 1",
            "top": 0.0,
            "width": 355.0
        }
    ]
}

GET /book/<fullname_or_name>/sheets/<sheet_name_or_ix>/charts/<chart_name_or_ix>

Example response:

{
    "chart_type": "line",

(continues on next page)
GET /book/<fullname_or_name>/sheets/<sheet_name_or_ix>/names

Example response:

```
{
  "names": [
    {
      "name": "Sheet1!myname1",
      "refers_to": "=Sheet1!$B$2:$C$3"
    }
  ]
}
```

GET /book/<fullname_or_name>/sheets/<sheet_name_or_ix>/names/<sheet_scope_name>

Example response:

```
{
  "name": "Sheet1!myname1",
  "refers_to": "=Sheet1!$B$2:$C$3"
}
```

GET /book/<fullname_or_name>/sheets/<sheet_name_or_ix>/names/<sheet_scope_name>/range

Example response:

```json
{
  "height": 211.0,
  "left": 0.0,
  "name": "Chart 1",
  "top": 0.0,
  "type": "chart",
  "width": 355.0
}
```
23.1 Top-level functions

xlwings.view(obj, sheet=None)

Opens a new workbook and displays an object on its first sheet by default. If you provide a sheet object, it will clear the sheet before displaying the object on the existing sheet.

Parameters

- **obj** *(any type with built-in converter)* – the object to display, e.g. numbers, strings, lists, numpy arrays, pandas dataframes
- **sheet** *(Sheet, default None)* – Sheet object. If none provided, the first sheet of a new workbook is used.

Examples

```python
>>> import xlwings as xw
>>> import pandas as pd
>>> import numpy as np
>>> df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
>>> xw.view(df)
```

New in version 0.7.1.
23.2 Object model

23.2.1 Apps

class xlwings.main.Apps(impl)

A collection of all app objects:

```python
>>> import xlwings as xw
>>> xw.app
Apps([<Excel App 1668>, <Excel App 1644>])
```

 active

Returns the active app.

New in version 0.9.0.

 add()

 count

Returns the number of apps.

New in version 0.9.0.

 keys()

Provides the PIDs of the Excel instances that act as keys in the Apps collection.

New in version 0.13.0.

23.2.2 App

class xlwings.App( visible=None, spec=None, add_book=True, impl=None )

An app corresponds to an Excel instance. New Excel instances can be fired up like so:

```python
>>> import xlwings as xw
>>> app1 = xw.App()
>>> app2 = xw.App()
```

An app object is a member of the apps collection:

```python
>>> xw.app
Apps([<Excel App 1668>, <Excel App 1644>])
>>> xw.app[0]
<Excel App 1668>
```

 Parameters

 - visible (bool, default None) – Returns or sets a boolean value that determines whether the app is visible. The default leaves the state unchanged or sets visible=True if the object doesn’t exist yet.
• **spec**(str, default None) – Mac-only, use the full path to the Excel application, e.g. `/Applications/Microsoft Office 2011/Microsoft Excel` or `/Applications/Microsoft Excel`

On Windows, if you want to change the version of Excel that xlwings talks to, go to Control Panel > Programs and Features and Repair the Office version that you want as default.

**Note:** On Mac, while xlwings allows you to run multiple instances of Excel, it’s a feature that is not officially supported by Excel for Mac: Unlike on Windows, Excel will not ask you to open a read-only version of a file if it is already open in another instance. This means that you need to watch out yourself so that the same file is not being overwritten from different instances.

**activate**(steal_focus=False)
Activates the Excel app.

**Parameters** **steal_focus**(bool, default False) – If True, make front-most application and hand over focus from Python to Excel.

New in version 0.9.0.

**api**
Returns the native object (pywin32 or appscript obj) of the engine being used.

New in version 0.9.0.

**books**
A collection of all Book objects that are currently open.

New in version 0.9.0.

**calculate()**
Calculates all open books.

New in version 0.3.6.

**calculation**
Returns or sets a calculation value that represents the calculation mode. Modes: 'manual', 'automatic','semiautomatic'

**Examples**

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> wb.app.calculation = 'manual'
```

Changed in version 0.9.0.

**display_alerts**
The default value is True. Set this property to False to suppress prompts and alert messages while code is running; when a message requires a response, Excel chooses the default response.
hwnd
Returns the Window handle (Windows-only).
New in version 0.9.0.

kill()
Forces the Excel app to quit by killing its process.
New in version 0.9.0.

macro(name)
Runs a Sub or Function in Excel VBA that are not part of a specific workbook but e.g. are part
of an add-in.

Parameters name (Name of Sub or Function with or without module name, e.g.
'Module1.MyMacro' or 'MyMacro')—

Examples

This VBA function:

```vba
Function MySum(x, y)
    MySum = x + y
End Function
```

can be accessed like this:

```python
>>> import xlwings as xw
>>> app = xw.App()
>>> my_sum = app.macro('MySum')
>>> my_sum(1, 2)
3
```

See also: Book.macro()

New in version 0.9.0.

pid
Returns the PID of the app.
New in version 0.9.0.

quit()
Quits the application without saving any workbooks.
New in version 0.3.3.

range(cell1, cell2=None)
Range object from the active sheet of the active book, see Range().
New in version 0.9.0.
**screen_updating**

Turn screen updating off to speed up your script. You won’t be able to see what the script is doing, but it will run faster. Remember to set the screen_updating property back to True when your script ends.

New in version 0.3.3.

**selection**

Returns the selected cells as Range.

New in version 0.9.0.

**version**

Returns the Excel version number object.

**Examples**

```python
>>> import xlwings as xw
>>> xw.App().version
VersionNumber('15.24')
>>> xw.apps[0].version.major
15
```

Changed in version 0.9.0.

**visible**

Gets or sets the visibility of Excel to True or False.

New in version 0.3.3.

### 23.2.3 Books

**class** `xlwings.main.Books(impl)`

A collection of all book objects:

```python
>>> import xlwings as xw
>>> xw.books  # active app
>>> xw.apps[0].books  # specific app
```

New in version 0.9.0.

**active**

Returns the active Book.

**add()**

**open (fullname)**

Opens a Book if it is not open yet and returns it. If it is already open, it doesn’t raise an exception but simply returns the Book object.
Parameters **fullname** *(str)* – filename or fully qualified filename, e.g. 
r'C:\path\to\file.xlsx' or 'file.xlsm'. Without a full path, it
looks for the file in the current working directory.

Returns **Book**

Return type  Book that has been opened.

### 23.2.4 Book

class *xlwings.Book*(**fullname**=None, **impl**=None)

A book object is a member of the `books` collection:

```python
>>> import xlwings as xw
>>> xw.books[0]
<Book [Book1]>
```

The easiest way to connect to a book is offered by `xw.Book`: it looks for the book in all app instances and returns an error, should the same book be open in multiple instances. To connect to a book in the active app instance, use `xw.books` and to refer to a specific app, use:

```python
>>> app = xw.App()  # or something like xw.apps[0] for existing apps
>>> app.books['Book1']
```

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>New book</td>
<td>xw.Book()</td>
</tr>
<tr>
<td>Unsaved book</td>
<td>xw.Book('Book1')</td>
</tr>
<tr>
<td>Book by (full)name</td>
<td>xw.Book(r'C:/path/to/file.xlsx')</td>
</tr>
<tr>
<td></td>
<td>xw.books['Book1']</td>
</tr>
<tr>
<td></td>
<td>xw.books.open(r'C:/path/to/file.xlsx')</td>
</tr>
</tbody>
</table>

Parameters **fullname** *(str, default None)* – Full path or name (incl. xlsx, xlsm etc.) of existing workbook or name of an unsaved workbook. Without a full path, it looks for the file in the current working directory.

`activate (steal_focus=False)`

Activates the book.

Parameters **steal_focus** *(bool, default False)* – If True, make front-most window and hand over focus from Python to Excel.

`api`

Returns the native object (pywin32 or appscript obj) of the engine being used.

New in version 0.9.0.

`app`

Returns an app object that represents the creator of the book.

New in version 0.9.0.
classmethod caller()
References the calling book when the Python function is called from Excel via RunPython. Pack it into the function being called from Excel, e.g.:

To be able to easily invoke such code from Python for debugging, use xw.Book.set_mock_caller().

New in version 0.3.0.

close()
Closes the book without saving it.

New in version 0.1.1.

fullname
Returns the name of the object, including its path on disk, as a string. Read-only String.

macro(name)
Runs a Sub or Function in Excel VBA.

Parameters name (Name of Sub or Function with or without module name, e.g. 'Module1.MyMacro' or 'MyMacro') –

Examples

This VBA function:

```python
Function MySum(x, y)
    MySum = x + y
End Function
```

can be accessed like this:

```python
>>> import xlwings as xw
>>> wb = xw.books.active
>>> my_sum = wb.macro('MySum')
>>> my_sum(1, 2)
3
```

See also: App.macro()

New in version 0.7.1.

name
Returns the name of the book as str.

names
Returns a names collection that represents all the names in the specified book (including all sheet-specific names).

Changed in version 0.9.0.
**static open_template()**

Creates a new Excel file with the xlwings VBA module already included. This method must be called from an interactive Python shell:

```python
>>> xw.Book.open_template()
```

See also: *Command Line Client*

New in version 0.3.3.

**save(path=None)**

Saves the Workbook. If a path is being provided, this works like SaveAs() in Excel. If no path is specified and if the file hasn’t been saved previously, it’s being saved in the current working directory with the current filename. Existing files are overwritten without prompting.

**Parameters**

- `path` *(str, default None)* – Full path to the workbook

**Example**

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> wb.save()
>>> wb.save(r'C:\path\to\new_file_name.xlsx')
```

New in version 0.3.1.

**selection**

Returns the selected cells as Range.

New in version 0.9.0.

**set_mock_caller()**

Sets the Excel file which is used to mock `xw.Book.caller()` when the code is called from Python and not from Excel via `RunPython`.

**Examples**

```python
# This code runs unchanged from Excel via RunPython and from Python directly
import os
import xlwings as xw

def my_macro():
    sht = xw.Book.caller().sheets[0]
    sht.range('A1').value = 'Hello xlwings!'

if __name__ == '__main__':
    xw.Book('file.xlsm').set_mock_caller()
    my_macro()
```

New in version 0.3.1.
sheets

Returns a sheets collection that represents all the sheets in the book.

New in version 0.9.0.

23.2.5 Sheets

class xlwings.main.Sheets(impl)

A collection of all sheet objects:

```python
>>> import xlwings as xw
>>> xw.sheets # active book
Sheets([<Sheet [Book1]Sheet1>, <Sheet [Book1]Sheet2>])
>>> xw.apps[0].books['Book1'].sheets # specific book
Sheets([<Sheet [Book1]Sheet1>, <Sheet [Book1]Sheet2>])
```

New in version 0.9.0.

active

Returns the active Sheet.

add(name=None, before=None, after=None)

Creates a new Sheet and makes it the active sheet.

Parameters

- **name** *(str, default None)* – Name of the new sheet. If None, will default to Excel’s default name.
- **before** *(Sheet, default None)* – An object that specifies the sheet before which the new sheet is added.
- **after** *(Sheet, default None)* – An object that specifies the sheet after which the new sheet is added.

23.2.6 Sheet

class xlwings.Sheet(sheet=None, impl=None)

A sheet object is a member of the sheets collection:

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> wb.sheets[0]
<Sheet [Book1]Sheet1>
>>> wb.sheets['Sheet1']
<Sheet [Book1]Sheet1>
>>> wb.sheets.add()
<Sheet [Book1]Sheet2>
```

Changed in version 0.9.0.
activate()
    Activates the Sheet and returns it.

api
    Returns the native object (pywin32 or appscript obj) of the engine being used.
    New in version 0.9.0.

autofit(axis=None)
    Autofits the width of either columns, rows or both on a whole Sheet.
    Parameters axis (string, default None) –
        • To autofit rows, use one of the following: rows or r
        • To autofit columns, use one of the following: columns or c
        • To autofit rows and columns, provide no arguments

Examples

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> wb.sheets['Sheet1'].autofit('c')
>>> wb.sheets['Sheet1'].autofit('r')
>>> wb.sheets['Sheet1'].autofit()
```

New in version 0.2.3.

book
    Returns the Book of the specified Sheet. Read-only.

cells
    Returns a Range object that represents all the cells on the Sheet (not just the cells that are currently in use).
    New in version 0.9.0.

charts
    See Charts
    New in version 0.9.0.

clear()
    Clears the content and formatting of the whole sheet.

clear_contents()
    Clears the content of the whole sheet but leaves the formatting.

delete()
    Deletes the Sheet.

index
    Returns the index of the Sheet (1-based as in Excel).
name

Gets or sets the name of the Sheet.

names

Returns a names collection that represents all the sheet-specific names (names defined with the “SheetName!” prefix).

New in version 0.9.0.

pictures

See Pictures

New in version 0.9.0.

range (cell1, cell2=None)

Returns a Range object from the active sheet of the active book, see Range().

New in version 0.9.0.

select ()

Selects the Sheet. Select only works on the active book.

New in version 0.9.0.

shapes

See Shapes

New in version 0.9.0.

used_range

Used Range of Sheet.

Returns

Return type xw.Range

New in version 0.13.0.

23.2.7 Range

class xlwings.Range (cell1=None, cell2=None, **options)

Returns a Range object that represents a cell or a range of cells.

Parameters

- **cell1 (str or tuple or Range)** – Name of the range in the upper-left corner in A1 notation or as index-tuple or as name or as xw.Range object. It can also specify a range using the range operator (a colon), e.g. ‘A1:B2’

- **cell2 (str or tuple or Range, default None)** – Name of the range in the lower-right corner in A1 notation or as index-tuple or as name or as xw.Range object.
Examples

Active Sheet:

```python
import xlwings as xw
xw.Range('A1')
xw.Range('A1:C3')
xw.Range((1,1))
xw.Range((1,1), (3,3))
xw.Range('NamedRange')
```

Specific Sheet:

```python
xw.books['MyBook.xlsx'].sheets[0].range('A1')
```

add_hyperlink (address, text_to_display=None, screen_tip=None)

Adds a hyperlink to the specified Range (single Cell)

**Parameters**

- **address** (*str*) – The address of the hyperlink.
- **text_to_display** (*str, default None*) – The text to be displayed for the hyperlink. Defaults to the hyperlink address.
- **screen_tip** (*str, default None*) – The screen tip to be displayed when the mouse pointer is paused over the hyperlink. Default is set to ‘<address> - Click once to follow. Click and hold to select this cell.’

    New in version 0.3.0.

**address**

Returns a string value that represents the range reference. Use `get_address()` to be able to provide parameters.

    New in version 0.9.0.

**api**

Returns the native object (pywin32 or appscript obj) of the engine being used.

    New in version 0.9.0.

**autofit ()**

Autofits the width and height of all cells in the range.

- To autofit only the width of the columns use `xw.Range('A1:B2').columns.autofit()`
- To autofit only the height of the rows use `xw.Range('A1:B2').rows.autofit()`

    Changed in version 0.9.0.

**clear ()**

Clears the content and the formatting of a Range.
clear_contents()
Clears the content of a Range but leaves the formatting.

color
Gets and sets the background color of the specified Range.
To set the color, either use an RGB tuple (0, 0, 0) or a color constant. To remove the background, set the color to None, see Examples.

Returns RGB
Return type tuple

Examples

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> xw.Range('A1').color = (255,255,255)
>>> xw.Range('A2').color = (255, 255, 255)
>>> xw.Range('A2').color = None
>>> xw.Range('A2').color is None
True
```
New in version 0.3.0.

column
Returns the number of the first column in the specified range. Read-only.

Returns
Return type Integer
New in version 0.3.5.

column_width
Gets or sets the width, in characters, of a Range. One unit of column width is equal to the width of one character in the Normal style. For proportional fonts, the width of the character 0 (zero) is used.
If all columns in the Range have the same width, returns the width. If columns in the Range have different widths, returns None.
column_width must be in the range: 0 <= column_width <= 255
Note: If the Range is outside the used range of the Worksheet, and columns in the Range have different widths, returns the width of the first column.

Returns
Return type float
New in version 0.4.0.
columns
Returns a `RangeColumns` object that represents the columns in the specified range.

New in version 0.9.0.

count
Returns the number of cells.

current_region
This property returns a Range object representing a range bounded by (but not including) any combination of blank rows and blank columns or the edges of the worksheet. It corresponds to Ctrl- on Windows and Shift-Ctrl-Space on Mac.

Returns
Return type Range object

direction
Returns a Range object that represents the cell at the end of the region that contains the source range. Equivalent to pressing Ctrl-Up, Ctrl-down, Ctrl-left, or Ctrl-right.

Parameters direction (One of 'up', 'down', 'right', 'left') –

Examples

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> xw.Range('A1:B2').value = 1
>>> xw.Range('A1').end('down')
<Range [Book1]Sheet1!$A$2>
>>> xw.Range('B2').end('right')
<Range [Book1]Sheet1!$B$2>
```

New in version 0.9.0.

expand (mode='table')
Expands the range according to the mode provided. Ignores empty top-left cells (unlike `Range.end()`).

Parameters mode (str, default 'table') – One of 'table' (=down and right), 'down', 'right'.

Returns
Return type Range

Examples

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> xw.Range('A1').value = [[None, 1], [2, 3]]
```
New in version 0.9.0.

**formula**

Gets or sets the formula for the given Range.

**formula_array**

Gets or sets an array formula for the given Range.

New in version 0.7.1.

**get_address** (*row_absolute=True, column_absolute=True, include_sheetname=False, external=False*)

Returns the address of the range in the specified format. `address` can be used instead if none of the defaults need to be changed.

**Parameters**

- `row_absolute` *(bool, default True)* – Set to True to return the row part of the reference as an absolute reference.

- `column_absolute` *(bool, default True)* – Set to True to return the column part of the reference as an absolute reference.

- `include_sheetname` *(bool, default False)* – Set to True to include the Sheet name in the address. Ignored if `external=True`.

- `external` *(bool, default False)* – Set to True to return an external reference with workbook and worksheet name.

**Returns**

**Return type** `str`

**Examples**

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> xw.Range((1,1)).get_address()
'$A$1'
>>> xw.Range((1,1)).get_address(False, False)
'A1'
>>> xw.Range((1,1), (3,3)).get_address(True, False, True)
'Sheet1!A$1:C$3'
>>> xw.Range((1,1), (3,3)).get_address(True, False, external=True)
'[Book1]Sheet1!A$1:C$3'
```

New in version 0.2.3.
height
Returns the height, in points, of a Range. Read-only.

Returns
Return type float
New in version 0.4.0.

hyperlink
Returns the hyperlink address of the specified Range (single Cell only)

Examples

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> xw.Range('A1').value
'www.xlwings.org'
>>> xw.Range('A1').hyperlink
'http://www.xlwings.org'
```

New in version 0.3.0.

last_cell
Returns the bottom right cell of the specified range. Read-only.

Returns
Return type Range

Example

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> rng = xw.Range('A1:E4')
>>> rng.last_cell.row, rng.last_cell.column
(4, 5)
```

New in version 0.3.5.

left
Returns the distance, in points, from the left edge of column A to the left edge of the range. Read-only.

Returns
Return type float
New in version 0.6.0.

name
Sets or gets the name of a Range.
New in version 0.4.0.

**number_format**

Gets and sets the number_format of a Range.

**Examples**

```python
>>> import xlwings as xw
>>> wb = xw.Book()
>>> xw.Range('A1').number_format
'General'
>>> xw.Range('A1:C3').number_format = '0.00%'
>>> xw.Range('A1:C3').number_format
'0.00%'
```

New in version 0.2.3.

**offset** *(row_offset=0, column_offset=0)*

Returns a Range object that represents a Range that’s offset from the specified range.

**Return type** Range

New in version 0.3.0.

**options** *(convert=None, **options)*

Allows you to set a converter and their options. Converters define how Excel Ranges and their values are being converted both during reading and writing operations. If no explicit converter is specified, the base converter is being applied, see *Converters and Options*.

**Parameters**

- **convert** *(object, default None)* – A converter, e.g. `dict`, `np.array`, `pd.DataFrame`, `pd.Series`, defaults to default converter

**Keyword Arguments**

- **ndim** *(int, default None)* – number of dimensions
- **numbers** *(type, default None)* – type of numbers, e.g. `int`
- **dates** *(type, default None)* – e.g. `datetime.date` defaults to `datetime.datetime`
- **empty** *(object, default None)* – transformation of empty cells
- **transpose** *(Boolean, default False)* – transpose values
- **expand** *(str, default None)* – One of 'table', 'down', 'right'

=> For converter-specific options, see *Converters and Options*.

**Returns**

**Return type** Range object

New in version 0.7.0.
**raw_value**

Gets and sets the values directly as delivered from/accepted by the engine that is being used (pywin32 or appscript) without going through any of xlwings’ data cleaning/converting. This can be helpful if speed is an issue but naturally will be engine specific, i.e. might remove the cross-platform compatibility.

**resize**(row_size=None, column_size=None)

Resizes the specified Range

**Parameters**

- **row_size** (*int > 0*) – The number of rows in the new range (if None, the number of rows in the range is unchanged).

- **column_size** (*int > 0*) – The number of columns in the new range (if None, the number of columns in the range is unchanged).

**Returns** Range object

**Return type** Range

New in version 0.3.0.

**row**

Returns the number of the first row in the specified range. Read-only.

**Returns**

**Return type** Integer

New in version 0.3.5.

**row_height**

Gets or sets the height, in points, of a Range. If all rows in the Range have the same height, returns the height. If rows in the Range have different heights, returns None.

row_height must be in the range: 0 <= row_height <= 409.5

Note: If the Range is outside the used range of the Worksheet, and rows in the Range have different heights, returns the height of the first row.

**Returns**

**Return type** float

New in version 0.4.0.

**rows**

Returns a RangeRows object that represents the rows in the specified range.

New in version 0.9.0.

**select**()

Selects the range. Select only works on the active book.

New in version 0.9.0.

**shape**

Tupel of Range dimensions.
New in version 0.3.0.

**sheet**

Returns the Sheet object to which the Range belongs.

New in version 0.9.0.

**size**

Number of elements in the Range.

New in version 0.3.0.

**top**

Returns the distance, in points, from the top edge of row 1 to the top edge of the range. Read-only.

Returns

**Return type** float

New in version 0.6.0.

**value**

Gets and sets the values for the given Range.

**Returns** object

**Return type** returned object depends on the converter being used, see `xlwings.Range.options()`

**width**

Returns the width, in points, of a Range. Read-only.

**Returns**

**Return type** float

New in version 0.4.0.

### 23.2.8 RangeRows

**class** `xlwings.RangeRows(rng)`

Represents the rows of a range. Do not construct this class directly, use `Range.rows` instead.

**Example**

```python
import xlwings as xw
rng = xw.Range('A1:C4')
assert len(rng.rows) == 4  # or rng.rows.count
rng.rows[0].value = 'a'
```

(continues on next page)
assert rng.rows(2) == xw.Range('A2:C2')

for r in rng.rows:
    print(r.address)

autofit()
    Autofits the height of the rows.

count
    Returns the number of rows.
    New in version 0.9.0.

23.2.9 RangeColumns

class xlwings.RangeColumns(rng)
    Represents the columns of a range. Do not construct this class directly, use Range.columns instead.

Example

import xlwings as xw
rng = xw.Range('A1:C4')

assert len(rng.columns) == 3  # or rng.columns.count
rng.columns[0].value = 'a'

assert rng.columns(2) == xw.Range('B1:B4')

for c in rng.columns:
    print(c.address)

autofit()
    Autofits the width of the columns.

count
    Returns the number of columns.
    New in version 0.9.0.
23.2.10 Shapes

class xlwings.main.Shapes (impl)
   A collection of all shape objects on the specified sheet:

   >>> import xlwings as xw
   >>> xw.books['Book1'].sheets[0].shapes
   Shapes([<Shape 'Oval 1' in <Sheet [Book1]Sheet1>>, <Shape 'Rectangle 1'
   in <Sheet [Book1]Sheet1>>])

   New in version 0.9.0.

   api
      Returns the native object (pywin32 or appscript obj) of the engine being used.

   count
      Returns the number of objects in the collection.

23.2.11 Shape

class xlwings.Shape (*args, **options)
   The shape object is a member of the shapes collection:

   >>> import xlwings as xw
   >>> sht = xw.books['Book1'].sheets[0]
   >>> sht.shapes[0]  # or sht.shapes['ShapeName']
   <Shape 'Rectangle 1' in <Sheet [Book1]Sheet1>>

   Changed in version 0.9.0.

   activate()
      Activates the shape.

      New in version 0.5.0.

   delete()
      Deletes the shape.

      New in version 0.5.0.

   height
      Returns or sets the number of points that represent the height of the shape.

      New in version 0.5.0.

   left
      Returns or sets the number of points that represent the horizontal position of the shape.

      New in version 0.5.0.

   name
      Returns or sets the name of the shape.

      New in version 0.5.0.
parent
Returns the parent of the shape.
New in version 0.9.0.

top
Returns or sets the number of points that represent the vertical position of the shape.
New in version 0.5.0.

type
Returns the type of the shape.
New in version 0.9.0.

width
Returns or sets the number of points that represent the width of the shape.
New in version 0.5.0.

23.2.12 Charts
class xlwings.main.Charts(impl)
A collection of all chart objects on the specified sheet:

```
>>> import xlwings as xw
>>> xw.books['Book1'].sheets[0].charts
Charts([<Chart 'Chart 1' in <Sheet [Book1]Sheet1>>, <Chart 'Chart 1' in <Sheet [Book1]Sheet1>>])
```
New in version 0.9.0.

add(left=0, top=0, width=355, height=211)
Creates a new chart on the specified sheet.

Parameters

- **left** *(float, default 0)* – left position in points
- **top** *(float, default 0)* – top position in points
- **width** *(float, default 355)* – width in points
- **height** *(float, default 211)* – height in points

Returns

Return type *Chart*

Examples
```python
>>> import xlwings as xw
>>> sht = xw.Book().sheets[0]
>>> sht.range('A1').value = [['Foo1', 'Foo2'], [1, 2]]
>>> chart = sht.charts.add()
>>> chart.set_source_data(sht.range('A1').expand())
>>> chart.chart_type = 'line'
>>> chart.name
'Chart1'
```

**api**
Returns the native object (pywin32 or appscript obj) of the engine being used.

**count**
Returns the number of objects in the collection.

### 23.2.13 Chart

**class** `xlwings.Chart(name_or_index=None, impl=None)`
The chart object is a member of the `charts` collection:

```python
>>> import xlwings as xw
>>> sht = xw.books['Book1'].sheets[0]
>>> sht.charts[0]  # or sht.charts['ChartName']
<Chart 'Chart 1' in <Sheet ['Book1']Sheet1>>
```

**api**
Returns the native object (pywin32 or appscript obj) of the engine being used.
New in version 0.9.0.

**chart_type**
Returns and sets the chart type of the chart.
New in version 0.1.1.

**delete()**
Deletes the chart.

**height**
Returns or sets the number of points that represent the height of the chart.

**left**
Returns or sets the number of points that represent the horizontal position of the chart.

**name**
Returns or sets the name of the chart.

**parent**
Returns the parent of the chart.
New in version 0.9.0.

**set_source_data(source)**
Sets the source data range for the chart.
Parameters `source` *(Range)* – Range object, e.g. `xw.books['Book1'].sheets[0].range('A1')`

top

Returns or sets the number of points that represent the vertical position of the chart.

width

Returns or sets the number of points that represent the width of the chart.

### 23.2.14 Pictures

class `xlwings.main.Pictures *(impl)*`

A collection of all picture objects on the specified sheet:

```python
>>> import xlwings as xw
>>> xw.books['Book1'].sheets[0].pictures
Pictures([<Picture 'Picture 1' in <Sheet [Book1]Sheet1>>, <Picture 'Picture 2' in <Sheet [Book1]Sheet1>>])
```

New in version 0.9.0.

`add(image, link_to_file=False, save_with_document=True, left=0, top=0, width=None, height=None, name=None, update=False)`

Adds a picture to the specified sheet.

**Parameters**

- `image` *(str or matplotlib.figure.Figure)* – Either a filepath or a Matplotlib figure object.
- `left` *(float, default 0)* – Left position in points.
- `top` *(float, default 0)* – Top position in points.
- `width` *(float, default None)* – Width in points. If PIL/Pillow is installed, it defaults to the width of the picture. Otherwise it defaults to 100 points.
- `height` *(float, default None)* – Height in points. If PIL/Pillow is installed, it defaults to the height of the picture. Otherwise it defaults to 100 points.
- `name` *(str, default None)* – Excel picture name. Defaults to Excel standard name if not provided, e.g. ‘Picture 1’.
- `update` *(bool, default False)* – Replace an existing picture with the same name. Requires name to be set.

**Returns**

**Return type** `Picture`

**Examples**

1. Picture
```python
>>> import xlwings as xw
>>> sht = xw.Book().sheets[0]
>>> sht.pictures.add(r'C:\path\to\file.jpg')
<Picture 'Picture 1' in <Sheet [Book1]Sheet1>>
```

2. Matplotlib

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.plot([1, 2, 3, 4, 5])
>>> sht.pictures.add(fig, name='MyPlot', update=True)
<Picture 'MyPlot' in <Sheet [Book1]Sheet1>>
```

api

Returns the native object (pywin32 or appscript obj) of the engine being used.

count

Returns the number of objects in the collection.

### 23.2.15 Picture

class xlwings.Picture(impl=None)

The picture object is a member of the `pictures` collection:

```python
>>> import xlwings as xw
>>> sht = xw.books['Book1'].sheets[0]
>>> sht.pictures[0]  # or sht.charts['PictureName']
<Picture 'Picture 1' in <Sheet [Book1]Sheet1>>
```

Changed in version 0.9.0.

api

Returns the native object (pywin32 or appscript obj) of the engine being used.

New in version 0.9.0.

delete()

Deletes the picture.

New in version 0.5.0.

height

Returns or sets the number of points that represent the height of the picture.

New in version 0.5.0.

left

Returns or sets the number of points that represent the horizontal position of the picture.

New in version 0.5.0.
name
Returns or sets the name of the picture.
New in version 0.5.0.

parent
Returns the parent of the picture.
New in version 0.9.0.

top
Returns or sets the number of points that represent the vertical position of the picture.
New in version 0.5.0.

update(image)
Replaces an existing picture with a new one, taking over the attributes of the existing picture.

Parameters
image (str or matplotlib.figure.Figure) – Either a filepath or a Matplotlib figure object.
New in version 0.5.0.

width
Returns or sets the number of points that represent the width of the picture.
New in version 0.5.0.

23.2.16 Names

class xlwings.main.Names(impl)
A collection of all name objects in the workbook:

```python
>>> import xlwings as xw
>>> sht = xw.books['Book1'].sheets[0]
>>> sht.names
[<Name 'MyName': =Sheet1!$A$3>]
```

New in version 0.9.0.

add(name, refers_to)
Defines a new name for a range of cells.

Parameters

- name (str) – Specifies the text to use as the name. Names cannot include spaces and cannot be formatted as cell references.
- refers_to (str) – Describes what the name refers to, in English, using A1-style notation.

Returns

Return type Name
New in version 0.9.0.
api
   Returns the native object (pywin32 or appscript obj) of the engine being used.
   New in version 0.9.0.

count
   Returns the number of objects in the collection.

23.2.17 Name

class xlwings.Name(impl)
The name object is a member of the names collection:

>>> import xlwings as xw
>>> sht = xw.books['Book1'].sheets[0]
>>> sht.names[0]  # or sht.names['MyName']
<Name 'MyName': =Sheet1!$A$3>

New in version 0.9.0.

api
   Returns the native object (pywin32 or appscript obj) of the engine being used.
   New in version 0.9.0.

delete()
   Deletes the name.
   New in version 0.9.0.

name
   Returns or sets the name of the name object.
   New in version 0.9.0.

refers_to
   Returns or sets the formula that the name is defined to refer to, in A1-style notation, beginning
   with an equal sign.
   New in version 0.9.0.

refers_to_range
   Returns the Range object referred to by a Name object.
   New in version 0.9.0.

23.3 UDF decorators

xlwings.func(category="xlwings", volatile=False, call_in_wizard=True)
   Functions decorated with xlwings.func will be imported as Function to Excel when running
   "Import Python UDFs".
category [int or str, default “xlwings”] 1-14 represent built-in categories, for user-defined categories use strings

New in version 0.10.3.

call_in_wizard [bool, default True] Set to False to suppress the function call in the function wizard.

New in version 0.10.3.

```
xlwings.sub()
Functions decorated with xlwings.sub will be imported as Sub (i.e. macro) to Excel when running “Import Python UDFs”.
```

```
xlwings.arg(arg, convert=None, **options)
Apply converters and options to arguments, see also Range.options().
Examples:
Convert x into a 2-dimensional numpy array:
```
```
import xlwings as xw
import numpy as np

@xw.func
@xw.arg('x', np.array, ndim=2)
def add_one(x):
    return x + 1
```

```
xlwings.ret(convert=None, **options)
Apply converters and options to return values, see also Range.options().
Examples
1. Suppress the index and header of a returned DataFrame:
```
```
import pandas as pd

@xw.func
@xw.ret(index=False, header=False)
def get_dataframe(n, m):
    return pd.DataFrame(np.arange(n * m).reshape((n, m)))
```

2. Dynamic array:
```
expand='table' turns the UDF into a dynamic array. Currently you must not use volatile functions as arguments of a dynamic array, e.g. you cannot use =TODAY() as part of a dynamic array. Also note that a dynamic array needs an empty row and column at the bottom and to the right and will overwrite existing data without warning.
```
Unlike standard Excel arrays, dynamic arrays are being used from a single cell like a standard function and auto-expand depending on the dimensions of the returned array:

```python
import xlwings as xw
import numpy as np

@xw.func
@xw.ret(expand='table')
def dynamic_array(n, m):
    return np.arange(n * m).reshape((n, m))
```

New in version 0.10.0.
